

DARK PARTICLES (BLACK HOLES WITH THE REDUCED PLANCK MASS) ANSWERS DARK ENERGY

John L. Haller Jr.
Hewlett Packard
jlhaller@gmail.com

Abstract:

This paper argues a hypothetical “dark” particle (a black hole with the reduced Planck mass) gives a simple explanation to the open question of dark energy and has a relic density of only 17% more than the commonly accepted value. By considering an additional near horizon boundary of the black hole, set by its quantum length, the black hole can obtain an arbitrary temperature. Black body radiation is still present and fits as the source of the Universe’s missing energy. Support for this hypothesis is offered by showing a stationary solution to the black hole’s length scale is the same if derived from a quantum analysis in continuous time, a quantum analysis in discrete time, or a general relativistic analysis.

INTRODUCTION

Cosmological observations early last century indicate the Universe is expanding. These observations show the speed at which objects move away from Earth have a strong correlation with their distance, known as Hubble’s Law. However it was not until the end of the last century when we had observations of Type Ia supernova that indicated the Universe is also accelerating [Liddle 2003].

The most popular explanation for these findings is an elusive energy density with an equation of state, $w < -1/3$ [Peebles & Ratra 2003] coined “Dark Energy” making up ~73% [Larson et al. 2010] of the energy density of the Universe. Many attempts have been made to explain dark energy’s origin [Rugh & Zinkernagel 2002], yet those attempts have ultimately been unsatisfying [Peebles & Ratra 2003, Greene 2004]. Many theories are still under review [Papantonopoulos 2007, Amendola & Tsujikawa 2010]; with the most accepted being the Lambda Cold Dark Matter model, Λ CDM where Lambda, the Cosmological Constant, provides a negative pressure $w = -1$ to the Universe [Liddle 2003, Peebles & Ratra 2003].

By hypothesizing a “dark particle” we begin to answer the question of the missing dark energy density. We will see a dark particle is a black hole with the reduced Planck mass. At this mass, the original assumption in Hawking’s work on black hole radiation [Hawking 1975] breaks down and I show how a quantum boundary, set by the width of the wavepacket, is larger than the event horizon. The surface gravity at this new quantum boundary is such that the temperature is arbitrary. Still the distribution of kinetic and potential energy is shown to be that of the black body.

We now have a source of a black body energy density that contributes to the energy density of the Universe. One might conclude that dark particles are in thermal equilibrium with the Cosmic Microwave Background, however I will argue the coupling mechanism between the dark particles and the background radiation field has been turned off since after the Dark Ages when re-ionization happened. If this is the case and if the dark particles temperature is frozen, they have an equation of state of $w = -1$ and the right relic density to explain dark energy.

It is also shown how the dark particle’s cool via a stationary diffusive process where the quantum solution to width of the wavepacket (the near horizon quantum boundary) is derived. I present this analysis in both continuous and discrete space-time and use a computer model to show the two give the same solution. A linkage between quantum mechanics and gravity is gained by considering three energy density terms of the dark particle. The resulting length scale, as solved by Friedmann’s equation, is identical to solution of its quantum length.

Section 1) argues a black hole with the reduced Planck mass (a dark particle) has an arbitrary temperature and that it’s density explains dark energy. Section 2) confirms that a dark particle’s energy is still in the form of black body radiation. Section 3) solves the length scale of a dark particle from a continuous quantum derivation and explains the mechanism by which the dark particle cools. Section 4) validates the solution to the length scale derived in section 3) by modeling the diffusive process in discrete space-time. Section 5) shows an identical solution to the length scale can also be derived from Friedmann’s equation when appropriate densities are considered. Section 6) discusses other similar work and how dark particles might solve other open questions as well.

1. MISSING ENERGY

1.1 DUAL GAUSSIANS

We begin by setting the context on a particle of mass m in equilibrium with a heat bath at temperature T . We assume a particle is in the dual Gaussian ground state.

$$x \sim p(x) dx = \frac{1}{\sqrt{2\pi(\Delta x_0)^2}} \cdot e^{-\frac{x^2}{2(\Delta x_0)^2}} dx$$

$$p_x \sim p(p_x) dp_x = \frac{1}{\sqrt{2\pi\Delta p_x^2}} \cdot e^{-\frac{p_x^2}{2\Delta p_x^2}} dp_x$$

Using the equipartition theorem on the kinetic energy [Feynmann 1965], one has

$$(\Delta p)^2 = mk_B T$$

And using Heisenberg's Uncertainty equation [Feynmann 1965],

$$(\Delta x_0)^2 = \frac{\hbar^2}{4(\Delta p)^2} = \frac{\hbar^2}{4mk_B T}$$

Making use of the equipartition theorem implies the particle is coupled to an ensemble of particles or heat bath [Gardiner & Zoller 2004]. The bath in this case is an external radiation field (for example the Cosmic Microwave Background). However as we will see the coupling between the dark particles and the heat back can be turned on or off with the presence or absence of neutral hydrogen atoms. We will use the temperature at the time of last coupling, and the particle's mass to define the width of the wavefunction.

1.2 BLACK HOLES

We will now apply these lengths to our understanding of black holes, specifically holes with a mass equal to the reduced Planck mass.

$$m = \sqrt{\frac{\hbar c}{8\pi G}}$$

A number of special conditions arise at this value of mass. First, the quantum limit, $dx = \hbar/2mc$ is equal to a circle's circumference with the Schwarzschild radius, Figure 1.

$$dx = \frac{\hbar}{2mc} = 2\pi R_S = 4\pi Gm$$

Indeed this is a small cross sectional area for the black hole.

Second, the Hawking temperature is equal to the mass of the black hole,

$$k_B T_{Hawking} = \frac{\hbar c^3}{8\pi Gm} = mc^2 = (4.34 \times 10^{-6} \text{ grams})c^2$$

Third, it is not clear that the Hawking temperature is valid at this value of the mass. Specifically Hawking stated in his seminal paper from 1975 [Hawking 1975], "Eventually, when the mass of the black hole is reduced to $10^{-5}g$, the quasi-stationary approximation will break down. At this point, one cannot continue to use the concept of a classical metric. However, the total mass or energy remaining in the system is very small."

Even more recent derivations of Hawking's work still breakdown at this mass [Barcelo et al 2011]. I will argue that when a black hole has the reduced Planck mass, the Hawking temperature breaks down because a secondary quantum boundary is greater than the Schwarzschild radius and it is this boundary that defines the near horizon's surface gravity. The length of the boundary is such that its surface gravity/temperature is arbitrary. I will also argue that even though "the total energy in the system is very small," it has just the right density (given the history of our Universe) to explain dark energy.

1.3 QUANTUM BOUNDARY

As the event horizon is defined by quantum limit, dx , the outer quantum boundary is defined by the square root of the position's variance (Δx_0). If Δx_0 defines the circumference of the boundary (like dx defines the circumference of the event horizon), the radius of the outer boundary will be R_{QB} , see figure 1.

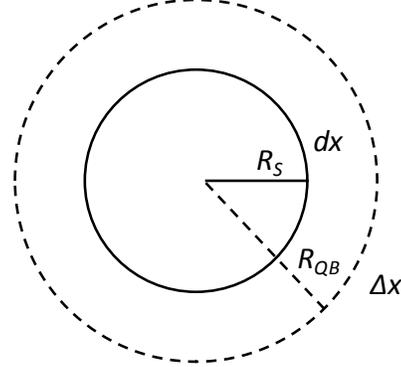

Figure 1: Event horizon and quantum boundary of black hole

$$R_{QB} = \frac{\Delta x_0}{2\pi} = \frac{\hbar}{4\pi\sqrt{mk_B T}}$$

The surface gravity at radius r is [Hayward 1998],

$$\kappa(r) = \frac{-1}{2} \frac{\partial}{\partial r} \left(-1 + \frac{2Gm}{c^2 r} \right) = \frac{Gm}{c^2 r^2}$$

The effective temperature [Hawking 1975] for surface gravity at radius R_{QB} will thus be,

$$T_{Dark Particle} = \frac{\kappa(R_{QB})\hbar}{2\pi k_B c} = \frac{8\pi Gm^2 T}{\hbar c} = T$$

The width of the black hole's wavepacket (which is set by the temperature of the heat bath) that defines the outer quantum boundary is just the right size to define a surface gravity such that the temperature is arbitrary and *not* a function of mass or other defining feature of the black hole. The temperature is its own independent parameter of the black hole. Thus I will call a black hole with the reduced Planck mass and arbitrary temperature a dark particle.

When the mass of a black hole is greater than the reduced Planck mass, the quantum boundary, R_{QB} is necessarily smaller than $R_{Schwarzschild}$ and thus it is $R_{Schwarzschild}$ that defines the surface gravity. When the black hole is a dark particle it can't lose any more mass lest it quantum limit will be larger than $R_{Schwarzschild}$ and it will cease to be a black hole. If the dark particle loses radiation it must shed its non-massive energy and thus decrease in temperature. On the flip side if the dark particle is in a heat bath at a higher temperature than the dark particle, it will match that larger temperature (assuming a coupling mechanism is in place) without gaining mass.

1.4 DARK ENERGY

Now hypothesize that a local group of dark particles are able to exchange heat with the Cosmic Microwave Background when neutral hydrogen atoms or other sinks are nearby to capture the

radiation from its gravitational binding but that they become frozen (constant temperature) when neutral hydrogen atoms are not nearby.

This hypothesis rests on the idea that positive virtual particle that leaves its pair becomes trapped by the outer quantum boundary even if it escapes the event horizon unless a sink is around to capture it. See figure 2. With no sink the net energy to escape is zero. However if a sink is around, like a neutral hydrogen atom, the sink can absorb radiation at one energy and release radiation into the dark particle at another energy, keeping it in thermal equilibrium.

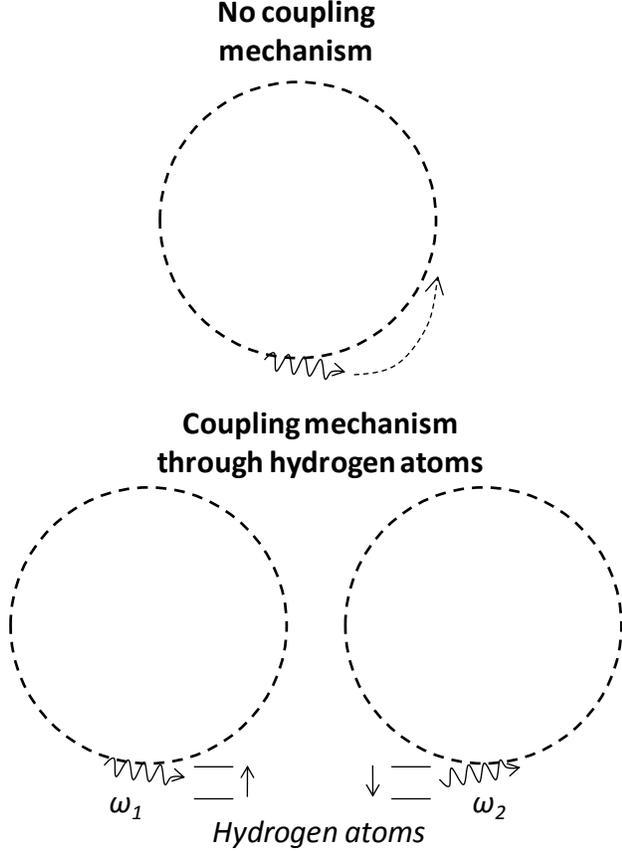

Figure 2: Without a coupling mechanism, the radiation can't obtain an escape trajectory thereby not allowing the dark particle to cool. However with a hydrogen atom or other sink the dark particle can equilibrate with the background radiation field.

During the dark ages, the time between decoupling and re-ionization [Barkana & Loeb 2001], the Universe was filled with hydrogen atoms that provided the coupling mechanism between the dark particles and regular energy. In these conditions the dark particles were coupled to the Cosmic Microwave Background (CMB). However after re-ionization, the hydrogen was ionized and the dark particles and its associated radiation energy density became frozen. The red-shift of re-ionization and the current temperature of the CMB provide an estimate of the temperature of the dark particles at the time of re-ionization where it remains constant up to today.

$$T_{DP} = (1 + z_{Re-ionization})T_{CMB-today} = constant$$

If we know the temperature of the dark particles at re-ionization, then we should have an idea for the total energy density that contributes to the Cosmological constant today.

$$\rho_{Dark\ Particles-BBR} = \frac{\pi^2 (k_B T_{DP})^4}{15 \hbar^3 c^5}$$

Because we have estimates of today's z value of re-ionization and today's temperature of the CMB we can estimate the density, ρ_{DP-BBR} . The Lambda Cold Dark Matter model, Λ CDM, provides a completely independent estimate of the density of dark energy, $\rho_{\Lambda CDM}$ [Liddle 2003], which we can estimate using the parameter, Ω_{Λ} , and today's Hubble constant.

$$\rho_{\Lambda CDM} = \Omega_{\Lambda} \cdot \rho_{critical} = \Omega_{\Lambda} \cdot \frac{3H^2}{8\pi G}$$

Using the 7 year Wilkinson Microwave Anisotropy Probe [Larson et al. 2010] as a source for our estimates Table 1 and Figure 3 shows how our model's estimate of dark energy is higher by 17% but well within the confidence range defined by $z_{re-ionization}$.

Table 1	Low	Average	High
ρ_{DP-BBR} (kg/m^3)	5.22E-27	8.12E-27	1.21E-26
T_{today} (degrees)	2.725	2.725	2.725
$z_{re-ionization}$	9.3	10.5	11.7
$\rho_{\Lambda CDM}$ (kg/m^3)	6.21E-27	6.95E-27	7.74E-27
H ($\frac{km}{sec \cdot Mpc}$)	68.5	71.0	73.5
Ω_{Λ}	0.705	0.734	0.763

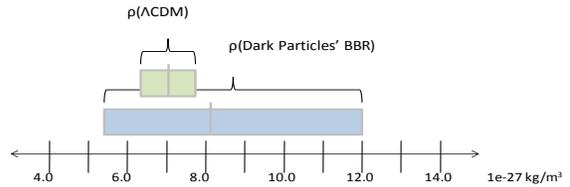

Figure 3: Visualization of density of dark energy from two models

1.5 INFLATION

It is also supportive to examine how this theory holds up to the inflationary period just after the big bang. The inflationary period that follows the grand unified period lasts for $\sim 10^{-34}$ seconds and during this time, the scale factor of the Universe grows exponentially by a factor of $\sim 10^{26}$ [Liddle & Lyth 2000]. Assuming that dark particles were able to release heat thereby maintaining equilibrium with the rest of the Universe's energy during the time of grand unification (immediately

preceding inflation), but that once the inflation period began the dark particles became isolated, then the dark particles will have a constant energy density during inflation leading to exponential expansion.

The theory also provides insights into reheating, the period after inflation. If you imagine the dark particles were at the temperature of grand unification at the beginning of the inflationary epoch only to become isolated, the dark particles would remain constant during the inflation while the rest of the energy density in the Universe would cool by a factor of $\sim(10^{26})^4$. If quarks, anti-quarks or gluons (which became available at the end of the inflationary period) are able to couple dark particles to the rest of the Universe's energy (like we hypothesized neutral hydrogen atoms are able to do), heat could flow from the hot dark particles back into the rest of the Universe, reheating it.

2. BLACK BODY RADIATION

With the derivation of the Hawking temperature breaking down at the reduced Planck mass, the derivation of black body radiation is also in question. However as we see below, a black hole with the reduced Planck mass still radiates a density of energy with the black body distribution.

2.1 RESISTIVE FORCE

We begin by assuming a quadratic potential energy term. If the equipartition theorem and Heisenberg Uncertainty principle hold [Feynmann 1965] we can derive the potential energy term. We have for one dimension,

$$PE = Cx^2$$

From the equipartition theorem,

$$\overline{PE} = \overline{KE} = \frac{k_B T}{2}$$

$$C\overline{x^2} = \frac{\overline{p^2}}{2m} = \frac{k_B T}{2}$$

If $\overline{x} = \overline{p} = 0$ and if $\Delta p \Delta x_0 = \hbar/2$, one can deduce the potential energy and the associated force

$$PE = \frac{mx^2}{2\tau^2}$$

$$F = \frac{-mx}{\tau^2}$$

Where $\tau = \hbar/2k_B T$.

In section 3 we show how this force is related to kinetic motion. Further in section 5 we show this resistive force can also be derived from the self gravitational potential of the particle and thus only acts over the distance defined by the Schwarzschild radius. Since the Schwarzschild radius is much smaller than the quantum step size of any particle we have experimental data on, we have never directly observed this effect.

2.2 ENERGY DENSITY

Pulling together the kinetic and potential energy terms for all three dimensions we have the energy of the 3-D oscillator

$$\hbar\omega = \frac{m}{2\tau^2}(x^2 + y^2 + z^2) + \frac{1}{2m}(p_x^2 + p_y^2 + p_z^2)$$

Again as the harmonic oscillator is in the ground state, we see our starting point with dual Gaussian wavefunctions is justified. Again solutions for position and momentum in the ground state are,

$$x \sim p(x)dx = \frac{1}{\sqrt{2\pi(\Delta x_0)^2}} \cdot e^{-\frac{x^2}{2(\Delta x_0)^2}} dx$$

$$p_x \sim p(p_x)dp_x = \frac{1}{\sqrt{2\pi\Delta p_x^2}} \cdot e^{-\frac{p_x^2}{2\Delta p_x^2}} dp_x$$

Where $(\Delta x_0)^2 = \hbar^2/4mk_B T$ and $\Delta p_x^2 = mk_B T$ obey Heisenberg's Uncertainty relation, and the Equipartition theorem [Feynmann 1965].

Thus the particle's wavefunction is isomorphic to a Wigner function of a point particle at $(x = 0, p = 0)$ squeezed to assure the equipartition theorem holds for both the kinetic and potential energy [Walls & Milburn 1994]. We can solve for the probability distribution on ω [Pan 2007].

$$\omega \sim p(\omega, T)d\omega = \frac{\hbar^3 \omega^2}{2(k_B T)^3} e^{-\frac{\hbar\omega}{k_B T}} d\omega$$

The average energy of this distribution is the three dimensional ground state energy of the harmonic oscillator, $3 \cdot \hbar \omega_0/2 = 3/2 \cdot \hbar \sqrt{\text{spring constant}/m} = 3k_B T$. However before we can associate this probability distribution with the internal radiation density, we must account for the fact that multiple photons can occupy the same state [Feynmann 1965]. Thus if M is the number of photons we have,

$$M \cdot \hbar\omega = \frac{6 \cdot k_B T}{2}$$

$$M \cdot \frac{m}{2} \left(\frac{x}{\tau}\right)^2 = M \cdot \frac{1}{2m} (p_x)^2 = \frac{k_B T}{2}$$

$$T \rightarrow \frac{T}{M}$$

And

$$p_{\text{radiation}}(\omega)d\omega = p\left(\omega, \frac{T}{M}\right)d\omega = \frac{M^3 \hbar^3 \omega^2}{2(k_B T)^3} e^{-\frac{M\hbar\omega}{k_B T}} d\omega$$

To deduce the radiation density from the probability distribution on the photons, one must divide by the surface area at $c\tau$, $A = 4\pi(c\tau)^2$ and multiply by $1/c$ times the power which in this case is $\hbar\omega$ divided by one period of the harmonic oscillator, $1/f_0 = 2\pi/\omega_0 = 2\pi\tau$

$$\rho_{\text{radiation-M}}(\omega)d\omega = \frac{\hbar\omega}{A \cdot c \cdot 2\pi\tau} p_{\text{radiation}}(\omega)d\omega$$

$$= \frac{\hbar\omega^3}{2\pi^2 c^3} e^{-\frac{M\hbar\omega}{k_B T}} d\omega$$

Lastly sum over all states of photons M from 1 to ∞ , and both degrees of polarization [Reif 1965] since all are possible.

$$\begin{aligned}\rho_{\text{radiation}}(\omega)d\omega &= \sum_{\text{pol}=1,-1} \sum_{M=1}^{\infty} \rho_{\text{radiation}-M}(\omega)d\omega \\ &= \frac{\hbar\omega^3 d\omega}{\pi^2 c^3} \sum_{M=1}^{\infty} e^{-\frac{M\hbar\omega}{k_B T}} = \frac{\hbar\omega^3}{\pi^2 c^3} \frac{1}{\left(e^{\hbar\omega/k_B T} - 1\right)} d\omega\end{aligned}$$

One will recognize the energy density of Black Body radiation, [Reif 1965].

3. QUANTUM SOLUTION (CONTINUOUS SPACE-TIME)

3.1 FREE PARTICLE DIFFUSION

We begin with the quantum diffusion of a free particle, which can be derived from the equations of motion [Gardiner & Zoller 2004]. With zero force and $m\dot{x} = p$ one can deduce,

$$x(t) = x_0 + \frac{p}{m}t$$

Calculating the variance and using Heisenberg's Uncertainty $\Delta p \Delta x_0 = \hbar/2$ we have,

$$(\Delta x)^2(t) = (\Delta x_0)^2 + \frac{\hbar}{m}t + \frac{(\Delta p)^2}{m^2} \cdot t^2$$

3.2 RESISTIVE FORCE

In section 2 we assumed a quadratic potential energy term and derived a resistive spring force. Here we will derive the same force but from kinematic arguments. If we look at the variance term that is linear in time from section 3.1 and compare it classical diffusion with a solution of $(\Delta x)^2(t)_{\text{classical}} = 2Dt$. We see an associated diffusion constant of $D = \hbar/(2m)$ which can also be derived from Einstein's kinetic theory where $D = k_B T \cdot \tau/m$ [Kubo 1966].

Exploring this diffusion constant further, we know D can also be represented as $D = \mu k_B T$ where $\mu = v/F$. If we consider that F is a viscous force retarding motion instead of driving motion then we have $\mu = -v/F$.

Consider the value of this classic linear diffusive term at $t = \tau$

$$2D\tau = \frac{\hbar}{m}\tau = \frac{\hbar^2}{2mk_B T}$$

Next rearrange the diffusion constant

$$2Dt = 2\mu k_B T t = \frac{-2vt}{F} k_B T$$

Replacing $x = vt$ and equating $2D\tau$ to $2Dt$ we have,

$$F = \frac{-mx}{\tau^2}$$

3.3 MODIFIED LANGEVIN EQUATION

With a particle no longer free we must re-solve for the variance using the Langevin equation. However contrary to the ordinary Langevin equation [Kubo 1966, Walls & Milburn 1994] we will change the assumption that the noisy driving force is uncorrelated with the particle's location. As we just derived, the force is anti-correlated with the position $F = -m\dot{x}/\tau^2$. The $1 - D$ equations of motion become,

$$m(\ddot{x}) = -\frac{m}{\tau}(\dot{x}) - \frac{m}{\tau^2}x$$

This equation can be used to solve $\overline{x^2}$ if one assumes the virial theorem [Feynmann 1965] where the average quadratic potential energy is equal to the average kinetic energy. The initial condition $\overline{x(\dot{x})}(t=0) = \hbar/2m$ is also assumed ensuring the equation's boundary conditions obey Heisenberg's Uncertainty. With calculus and the chain rule, one has,

$$\overline{x^2} = \frac{\hbar^2}{2mk_B T} \left(1 - e^{-2k_B T t/\hbar}\right) = 2D\tau \left(1 - e^{-t/\tau}\right)$$

This version of the Langevin equation has the familiar $2D\tau$ term however it represents a stationary process where the ordinary Langevin equation is non-stationary.

3.4 STATIONARY DIFFUSION

The quantum solution from the modified Langevin presented in section 3.3 is very interesting for two reasons. First off it has a finite asymptotic value which is what we would expect for a quantum solution to a black hole. We would expect that a black hole has a finite width to it and the outward diffusive pressure is balanced by an inward gravitational pressure.

Secondly we notice the asymptotic variance of position is twice that of $(\Delta x_0)^2$. This represents the dark particle cooling. As the particle diffuses out to $2(\Delta x_0)^2$ the temperature cools to $T/2$ and the total energy in the oscillator goes from $3k_B T$ to $3k_B T/2$. This is also where the particle gets the energy needed to radiate. The energy transfers over to the radiation field when the dark particle's wavefunction collapses as the photon is created. After the photon releases, the dark particle begins to diffuse again now at temperature of $T/2$.

To remain consistent with our analysis above, if the photon is not collected by a neutral hydrogen atom before the next cycle of the harmonic oscillator begins, the photon will be re-absorbed, the dark particles' position will become fuzzy again and it will regain its energy and maintain its original temperature T .

4. QUANTUM SOLUTION (DISCRETE SPACE-TIME)

4.1 DISCRETE SPACE-TIME

Adding credibility to the modified Langevin equation, I simulate the outcome. Discrete space-time has been around for a while [Forsythe & Wasow 1960] and is becoming even more important [Mecklenburg & Regan 2011]. To derive the correct model and the correct parameters for the model we will start with what we know.

4.2 STANDARD BERNOULLI PROCESS

The standard Bernoulli process is thoroughly reviewed by Reif [1965] and Chandrasekhar [1943]. In the standard Bernoulli process a particle steps to the left or steps to the right a distance δx with probability $\beta, 1 - \beta$ respectively at every time step δt . To derive the spatial step size, δx , we look at the variance as a function of the number of steps, K , and compare it to the continuous solution.

$$(\Delta x)_K^2 = \delta x^2 K$$

From Dirac's solution to the eigenvalue of the velocity [Dirac 1958] of a particle we know, $\delta x = c \delta t$, and since $t = K \delta t$, we have,

$$(\Delta x)_K^2 = \delta x \cdot c \cdot t$$

From the continuous linear solution $(\Delta x)^2(t) = \hbar t/m$ one deduces,

$$\delta x = \frac{\hbar}{mc}$$

4.3 BERNOULLI PROCESS WITH RESISTIVE FORCE

We can now proceed to modify the standard Bernoulli processes to account for the resistive force we found in the continuous case. We will find this discrete solution is equal to the modified continuous Langevin equation.

To begin with we need to match the continuous 1-D force, $F = -mx/\tau^2$ with the ensemble average force experienced by the discrete case. The ensemble average force felt in the discrete case is the probability the particle experiences a positive change in momentum times the impacted force $\Delta p/\delta t$ plus the probability the particle experiences a negative change in momentum times $-\Delta p/\delta t$. We can solve for the probability β as a function of x by examining the ensemble average discrete force on the particle felt at the location x during time τ .

$$F_{discrete}(x) = \beta(x) \frac{\Delta p}{\delta t} + (1 - \beta(x)) \frac{-\Delta p}{\delta t}$$

However before we can compare $F_{discrete}(x)$ to $F = -mx/\tau^2$ we have to account for a factor of 2 that arises because in the continuous case the force is constant but in the discrete case the force is delta function impact to the momentum. As shown in figure 4 the distance a particle moves under the continuous force F is $x = F \cdot \delta t^2/2m$, however the distance a particle moves under the discrete force $F_{discrete}$ is $x = F_{discrete} \cdot \delta t^2/m$. Thus we need to set $2F_{discrete} = F$.

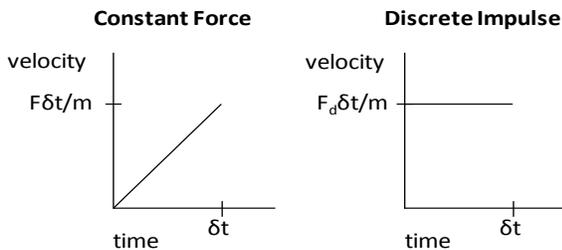

Figure 4: Shows the difference between a continuous constant force and a discrete impulse force. If the distances displaced are equal, the discrete force only need be half as strong.

Solving for $\beta(x)$ we have,

$$\beta(x) = \frac{1}{2} \left(1 - \frac{mx \cdot \delta t}{2\Delta p \cdot \tau^2} \right)$$

We can reduce this further since we know Δp and δt . Since we are dealing with the harmonic oscillator the only energy transition can be in multiples of the quantized energy of the oscillator, $\omega_0 = 2k_B T$. Thus a change in momentum Δp must be equal to $2k_B T/c$; δt can also be replaced by \hbar/mc^2 as described above.

$$\beta(x) = \frac{1}{2} \left(1 - \frac{x \cdot k_B T}{\hbar c} \right)$$

This is saying that the probability a particle steps to the right is a function of the distance the particle is away from the center position $x = 0$. We can see why the dark particle is stationary or why a photon released from the dark particle can't escape unless it is a distance 2τ away from the center.

The best way to show how this works is through a model where we show the variance of the position is equal to that of the modified continuous Langevin equation.

4.4 COMPUTER MODEL

The following Matlab code shows the discrete model gives the same solution as the continuous modified Langevin. See figure 5 and 6

5. FRIEDMANN'S EQUATION SOLUTIONS

We now show that by combining the energy density with three different equations of state, $w = -1, -1/3, \text{ and } 1/3$ we arrive at the same solution as what was derived in both the continuous and discrete quantum solutions. The solutions to Friedmann's equation with the densities standing alone for two out of the three equations of state also correspond to the solutions to the linear and quadratic time terms of the variance when the particle is free. We need to assume the particles comes as pairs such

that we can define a general relativistic length scale L and a quantum mechanical length scale ℓ .

5.1 LENGTH SCALES

We define L as twice the light time τ , the maximum distance two particles can traverse in time τ .

$$L \equiv 2\tau c = \frac{\hbar c}{k_B T}$$

We define ℓ as the variance between the two particles. If the two have independent wavefunctions we have

$$\ell \equiv \sqrt{2} \cdot \Delta x$$

Using these two definitions we will show that under three different equations of state L (the solution to Friedmann's equation) will be equal to ℓ (the variance of quantum diffusion).

5.2 EQUATION OF STATE, $w = 1/3$

First for the equation of state $w = 1/3$, we have the energy in the 3-D oscillator

$$\hbar\omega = \frac{m}{2\tau^2}(x^2 + y^2 + z^2) + \frac{1}{2m}(p_x^2 + p_y^2 + p_z^2)$$

We begin with the probability distribution on $\omega \sim p(\omega, T)d\omega$ from section 2.2

$$\omega \sim p(\omega, T)d\omega = \frac{\hbar^3 \omega^2}{2(k_B T)^3} e^{-\frac{\hbar\omega}{k_B T}} d\omega$$

Since we are no longer talking about photons/bosons like above, but are talking about fermions we don't have to account for multiple particles. The average energy of this distribution is the three dimensional ground state energy of the harmonic oscillator, $3k_B T$.

If we consider a volume $V = L^3$ the energy density is

$$\rho_{w=1/3}(L) = \frac{3k_B T}{c^2(L)^3} = \frac{3\hbar}{c(L)^4}$$

The Friedmann equation when the density is dominated by this equation of state, $w = 1/3$ becomes,

$$\left(\frac{\dot{L}}{L}\right)^2 = \frac{8\pi G}{3} \rho_{w=1/3}(L) = \frac{8\pi G \hbar}{c(L)^4}$$

Solving for $L(t)$

$$L_{w=1/3}^2 = \left(\frac{32\pi G \hbar}{c}\right)^{1/2} t = \frac{2\hbar}{m} t = \ell_{linear}^2$$

5.3 EQUATION OF STATE, $w = -1/3$

In deriving the density and solution for this equation of state we turn to a derivation of Friedmann's equation [Liddle 2003]. We will start by deriving the gravitational explanation of the resistive spring force. Equating the average gravitational potential energy to $3k_B T/2$ for 3 dimensions gives,

$$\overline{PE}_{gravity} = \frac{-GMm}{r} = \frac{3k_B T}{2}$$

When $M = 4\pi r^3 \rho/3$

$$\frac{-GMm}{r} = \frac{-4\pi G \rho m r^2}{3}$$

Due to symmetry we can re-write $\overline{r^2}$ as $3(\Delta x_0)^2 = 3\hbar^2/4mk_B T$ [Feynmann 1965] to arrive at,

$$\frac{-8\pi G \rho}{3} = \frac{(2k_B T)^2}{\hbar^2}$$

Plugging this back into the relationship between potential energy and force [Feynmann 1965] and with time constant $\tau = \hbar/2k_B T$ we have,

$$F_r = \frac{-d}{dr} PE = \frac{-d}{dr} \left(\frac{-GMm}{r} \right) = \frac{-d}{dr} \left(\frac{-4\pi G \rho m r^2}{3} \right) = \frac{8\pi G \rho m r}{3}$$

$$= \frac{-4m(k_B T)^2}{\hbar^2} r = \frac{-mr}{\tau^2}$$

When a particle moves within the space curved by the black hole, a resistive spring force is in play. Here we see a gravitational explanation for the spring force.

Going back to solve for L we have,

$$\frac{-4\pi G \rho m \overline{r^2}}{3} = \frac{3k_B T_0}{2}$$

Where T_0 is constant. With $\overline{r^2} = 3(\Delta x_0)^2 = 3\ell^2/2$ and m the reduced Planck mass, the density is

$$\rho_{w=-1/3} = \frac{-6mk_B T_0}{\hbar c(\ell)^2}$$

Friedmann's equation when $\ell = L$ and its solution are,

$$\left(\frac{\dot{L}}{L} \right)^2 = \frac{8\pi G}{3} \rho_{w=-1/3}(\ell = L) = \frac{-2k_B T_0}{m(L)^2}$$

$$L_{w=1/3}^2 = \left(\frac{-2k_B T}{m} \right) t^2 = -\ell_{quadratic}^2$$

Notice the solution of $L_{w=-1/3}$ is imaginary because of the positive curvature associated with this equation of state [Liddle 2003]. Yet we still have $|L| = |\ell|$. In the next two paragraphs we derive the holistic energy density, $\rho_{\text{dark partilce}}$ which is always positive and thus $L_{\text{dark partilce}}$ is real.

The last term we need is a constant energy density, $w = -1$. To solve for the constant density, we insert $L_0 = \hbar/\sqrt{mk_B T_0}$ (which we show is the asymptotic value of the solution) into the density of the oscillator.

$$\rho_{w=-1} = \rho_{w=1/3}(L = L_0) = \frac{3\hbar}{c(L_0)^4} = \frac{3m^2(k_B T_0)^2}{c\hbar^3}$$

The solution to Friedmann's equation with this density is exponentially increasing, however if we add this density term to our other two densities we see the solution is equal to the solution of the Langevin equation.

$$\rho_{\text{dark partilce}} = \rho_{w=-1} + \rho_{w=-1/3} + \rho_{w=1/3}$$

$$\rho_{DP}(L) = \frac{3}{\hbar c} \left(\frac{\hbar^2}{(L(t))^4} - \frac{2mk_B T_0}{(L(t))^2} + \frac{m^2(k_B T_0)^2}{\hbar^2} \right)$$

With a little calculus the solution to Friedmann's equation with this density is

$$\left(\frac{\dot{L}}{L} \right)^2 = \frac{8\pi G}{3} \rho_{DP}(L) = \left(\frac{\hbar}{mL^2} - \frac{k_B T_0}{\hbar} \right)^2$$

$$L_{DP}^2 = \frac{\hbar^2}{mk_B T_0} \left(1 - e^{-2k_B T_0 t / \hbar} \right)$$

With $k_B T_0 = \hbar/(2\tau_0)$ and the $D = \hbar/(2m)$, this is re-written,

$$L_{DP}^2 = 4D\tau_0 \left(1 - e^{-t/\tau_0} \right) = \ell_{Langevin}^2$$

We see the solutions to Friedmann's equation and the equations of quantum diffusion behave in the same way. It is interesting to note that the density vanishes at the asymptotic value $\rho_{DP}(L_0) = 0$ so we don't have to worry about this fermionic density contributing to the cosmological constant.

6.0 DISCUSSION

A similarity one might find with other current work would be Primordial Black Hole Remnants (PBHR). Chen uses PBHRs to nicely explain dark matter [Chen 2004]. Interpreted here the density of state is determined by how the density scales as a function of the length scale. We have suggested that when the dark particles cannot couple to ordinary matter the temperature and thus density is frozen, implying a density of state of $w = -1$ and explaining dark energy. However if the dark particles are near neutral hydrogen atoms (i.e. near galaxies), allowing them to couple and release heat, the density of state could be positive and the acceleration equation would be positive, more in line with dark matter [Liddle 2003].

A test of the hypothesis that if neutral hydrogen atoms are near, dark particles act like more like dark matter than dark energy would be to look for cosmological observations where we observe either bountiful or scanty amount of neutral hydrogen. Perhaps Virgo21 (where we observe neutral hydrogen atoms and possibly a high density of dark matter) [Minchin et al. 2007] or global clusters (where any neutral atoms would be ionized and almost no dark matter) [Mashchenko & Sills 2005] could serve as a first validation.

A further validation of this hypothesis might be experimentally possible on Earth. A team led by Perl [Adler & Mueller & Perl 2011] has suggested two identical side by side atom interferometers could reveal a dark energy density by measuring the time it takes for atoms to fall through gravity, respectively between the two interferometers. One could build on this approach and artificially alter the density of the dark particles by surrounding each interferometer in a bath of neutral

hydrogen atoms (or other suitable sink that is not dangerous at high temperatures). One bath could be kept at a low temperature and the other at a high temperature. If the bath was large enough to allow the neutral hydrogen and the dark particles to couple and exchange heat before the dark energy reference frame moves past the interferometers [Adler & Mueller & Perl 2011], the density of dark particles that interacts with the falling atoms would be different between the hot and the cold interferometers and the difference would be measured.

Questions still remain, like the exact mechanism for how the dark particle exchanges heat, and more analysis is needed for dark particles to fully answer the questions of dark energy [Peebles & Ratra 2003, Green 2004] or for that matter other open questions like dark matter [Bertone & Silk 2010]. Yet this initial brief report is intended to set the physical parameters and give guidance for how the forces of gravity and quantum mechanics work together and have complementary solutions in a simple straightforward way.

While it is not possible to artificially create a particle with the reduced Planck mass, it would explain why prior experiments have been unable to locate the missing energy.

As a note, the dark particle was built out of research in Finite Difference Time Domain (FDTD) modeling of diffusive motion [Forsythe & Wasow 1960, Haerendell 1968]. By noticing a connection between Bernoulli's process [Reif 1965, Chandrasakhar 1943] and black body radiation [Reif 1965] it was possible to derive the continuous version of the theory. Application to Friedmann's equation followed a need to explain the resistive spring force that keeps the particle stationary. When the theory suggested a density of black body radiation was hidden (because the cross section of the dark particle is on the order of the Planck length) the tie to dark energy was made.
