# A PROOF OF RIEMANN HYPOTHESIS USING THE GROWTH OF MERTENS FUNCTION M(x)

#### YOUNG-MOOK KANG

ABSTRACT. A study of growth of M(x) as  $x \to \infty$  is one of the most useful approach to the Riemann hypophotesis(RH). It is very known that the RH is equivalent to which  $M(x) = O(x^{1/2+\varepsilon})$  for  $\varepsilon > 0$ . Also Littlewood proved that "the RH is equivalent to the statement that  $\lim_{x\to\infty} M(x)x^{-1/2-\varepsilon} = 0$ , for every  $\varepsilon > 0$ ".[1] To use growth of M(x) approaches zero as  $x \to \infty$ , I simply prove that the Riemann hypothesis is valid. Now Riemann hypothesis is not hypothesis any longer.

# 1. INTRODUCTION

The Riemann zeta-function  $\zeta(s)$  is the function of complex numbers  $s \ (s \neq 1)$ . There are infinitely many zeros at the negative even integers such that at  $(s = -2, s = -4, s = -6, \cdots)$  These are called the trivial zeros. The Riemann hypothesis(RH) is related the non-trivial zeros, and states that:

"All non-trivial zeros of Riemann zeta-function  $\zeta(s)$  have real part  $\frac{1}{2}$ ."

The RH has been implied strong bounds on the growth of many arithmetic functions. Among them, our most interesting function is Mertens function.

1.1. Mertens function : M(n) is defined as follows :

$$M(n) = \sum_{k=1}^{n} \mu(k)$$

where  $\mu(k)$  is the Möbius function. [1, 2]

The inverse of the Riemann zeta function is expressed that the Dirichlet series generates the Möbius function by Euler product.

(1.1) 
$$\frac{1}{\zeta(s)} = \prod_{p_k}^{\infty} (1 - \frac{1}{p_k^s}) = \sum_{n=1}^{\infty} \frac{\mu(n)}{n^s}$$

where  $\Re(s) > 1$ ,  $p_k$  is the k-th prime number

Mertens function, M(x) is closely linked with the positions of zeroes of the Riemann zeta-function,  $\zeta(s)$ . When we define M(0) = 0, their relation is expressed as follows : [3]

$$\frac{1}{\zeta(s)} = \sum_{n=1}^{\infty} \frac{\mu(n)}{n^s} = \sum_{n=1}^{\infty} \frac{M(n) - M(n-1)}{n^s}$$

Key words and phrases. Riemann hypothesis, Mertens function, Möbius function, Golden key, Denjoy Probabilistic Interpretation.

#### YOUNG-MOOK KANG

$$=\sum_{n=1}^{\infty} \frac{M(n)}{n^s} - \sum_{n=1}^{\infty} \frac{M(n-1)}{(n)^s} = \sum_{n=1}^{\infty} \frac{M(n)}{n^s} - \sum_{n=1}^{\infty} \frac{M(n)}{(n+1)^s}$$
$$=\sum_{n=1}^{\infty} M(n) \left(\frac{1}{n^s} - \frac{1}{(n+1)^s}\right) = \sum_{n=1}^{\infty} M(n) \int_n^{n+1} \frac{s}{x^{s+1}} dx$$
$$= s \sum_{n=1}^{\infty} \int_n^{n+1} \frac{M(x)}{x^{s+1}} = s \int_1^{\infty} \frac{M(x)}{x^{s+1}} dx$$

since M(x) is constant on each interval [n, n+1)

(1.2) 
$$\frac{1}{\zeta(s)} = s \int_1^\infty M(x) x^{-s-1} dx$$

The equation (1.2) shows that a relation of the Mertens function and zeros of the Riemann zeta-function very well.[3]

If  $|M(x)| < C|x^{1/2}|$  for C > 0, then

$$|\frac{M(x)}{x^{s+1}}| < |\frac{C\sqrt{x}}{x^{s+1}}| = \frac{C}{\sqrt{x}}|\frac{1}{x^s}| = \frac{C}{\sqrt{x}}\frac{1}{x^{\Re(s)}} = \frac{C}{x^{\Re(s)+1/2}}$$

This means that  $\Re(s) > 1/2$  because, the right integral in equation (1.2) would converge provided which  $\Re(s) + 1/2 > 1$ . According to this result, it can define a function analytic in  $\Re(s) > 1/2$  and extend an analytic continuation of  $1/\zeta(s)$ from  $\Re(s) > 1$  to  $\Re(s) > 1/2$ . It means that  $\zeta(s)$  have no zeros for  $\Re(s) > 1/2$ and also for  $\Re(s) < 1/2$  by symmetry. Thus, all non-trivial zeros must have real part one-half.[3]  $|M(x)| < C|x^{1/2}|$  called Mertens conjecture is a condition stronger than RH. Actually, the RH is equivalent to a condition that  $M(x) = O(x^{1/2+\varepsilon})$  for all  $\varepsilon > 0.[2, 4]$  Also according to a chapter 12 in the reference[1], a necessary and sufficient condition for the RH is

(1.3) 
$$\lim_{x \to \infty} \frac{M(x)}{x^{1/2+\varepsilon}} = 0, \text{ for every } \varepsilon > 0 \text{ , proven by Littlewood.}$$

I just will prove that equation (1.3) is valid using the growth of M(x), for a proof of the RH.

# 2. The Growth of Mertens Function

While I was studying about the growth of M(x) as  $x \to \infty$ , I found a fact that the equation (1.1) is very similar to  $\sum_{n=1}^{\infty} \mu(n)$ .

$$\sum_{n=1}^{\infty} \frac{\mu(n)}{n^s} = \prod_{p_k}^{\infty} (1 - \frac{1}{p_k^s})$$
VS
$$\sum_{n=1}^{\infty} \mu(n) = ???$$

If we can remove  $\frac{1}{n^s}$  in the equation (1.1), can we know about  $\sum_{n=1}^{\infty} \mu(n)$ ? The solution was found very easily. Look at the equation (2.1).

(2.1)  $\prod_{k=1}^{\infty} (1 - \frac{p_k}{p_k}) = 0$ , where  $p_k$  is the k-th prime number.

Actually, it is seem that means nothing at all. However, I want to call that it is one of the Golden Keys for opening locked RH. Because, it shows that the growth of M(x) approaches zero as  $x \to \infty$ .

Theorem 2.1. A Golden Key of the Riemann Hypothesis

$$\prod_{k=1}^{\infty} (1 - \frac{p_k}{p_k}) = \sum_{n=1}^{\infty} \mu(n) = \lim_{n \to \infty} M(n) = 0$$

 $\infty$ 

Proof.

$$\begin{split} \prod_{k=1}^{\infty} (1 - \frac{p_k}{p_k}) &= 0 \\ &= (1 - \frac{2}{2})(1 - \frac{3}{3})(1 - \frac{5}{5})(1 - \frac{7}{7})(1 - \frac{11}{11})(1 - \frac{13}{13})(1 - \frac{17}{17})(1 - \frac{19}{19})\dots \\ &= 1 - \frac{2}{2} - \frac{3}{3} - \frac{5}{5} + \frac{6}{6} - \frac{7}{7} + \frac{10}{10} - \frac{11}{11} - \frac{13}{13} + \frac{14}{14} + \frac{15}{15} - \frac{17}{17} - \frac{19}{19} + \frac{21}{21} + \dots \\ &= 1 + \frac{-2}{2} + \frac{-3}{3} + \frac{0}{4} + \frac{-5}{5} + \frac{6}{6} + \frac{-7}{7} + \frac{0}{8} + \frac{0}{9} + \frac{10}{10} + \frac{-11}{11} + \frac{0}{12} + \frac{-13}{13} + \frac{14}{14} + \frac{15}{15} + \frac{0}{16} + \dots \\ &= \frac{1\mu(1)}{1} + \frac{2\mu(2)}{2} + \frac{3\mu(3)}{3} + \frac{4\mu(4)}{4} + \frac{5\mu(5)}{5} + \frac{6\mu(6)}{6} + \frac{7\mu(7)}{7} + \frac{8\mu(8)}{8} + \frac{9\mu(9)}{9} + \frac{10\mu(10)}{10} + \dots \\ &= \sum_{n=1}^{\infty} \frac{n\mu(n)}{n} = \sum_{n=1}^{\infty} \mu(n) = \lim_{n \to \infty} M(n) = 0 \end{split}$$

How do you think about the convergence of the growth of M(x)? Maybe most people have believed that the growth of M(x) must be diverged as  $x \to \infty$ . However, the theorem (2.1) shows that the growth of M(x) approaches zero as  $x \to \infty$ .

# 3. The Probability of Möbius Function

The theorem (2.1) shows some results about probability of Möbius function as following :

Corollary 3.1.

$$Pr(\mu(n) = +1) = Pr(\mu(n) = -1)$$

where n is the natural number.

Proof.

Because, 
$$\lim_{n \to \infty} M(n) = 0$$

Therefore, the numbers of -1 and +1 of  $\mu(n)$  are equal.

# Corollary 3.2.

$$Pr(\mu(n) = +1) = \frac{3}{\pi^2}$$
,  $Pr(\mu(n) = -1) = \frac{3}{\pi^2}$  and  $Pr(\mu(n) = 0) = 1 - \frac{6}{\pi^2}$ 

where n is the natural number.

Proof.

4

Using the inclusion-exclusion principle,

a probability of the total square-free numbers is defined as follows :

$$Pr(\mu(n) \neq 0) = (1 - \frac{1}{2^2})(1 - \frac{1}{3^2})(1 - \frac{1}{5^2})(1 - \frac{1}{7^2})(1 - \frac{1}{11^2})\cdots$$
$$= \prod_{k=1}^{\infty} (1 - \frac{1}{p_k^2}) = \frac{1}{\zeta(2)} = \frac{6}{\pi^2}$$
Because,  $Pr(\mu(n) = -1) = Pr(\mu(n) = +1)$ 

and

$$Pr(\mu(n) = -1) + Pr(\mu(n) = +1) + Pr(\mu(n) = 0) = 1$$
  
Therefore,  $Pr(\mu(n) = +1) = \frac{3}{\pi^2}$ ,  $Pr(\mu(n) = -1) = \frac{3}{\pi^2}$ ,  $Pr(\mu(n) = 0) = 1 - \frac{6}{\pi^2}$ 

Denjoy's proposal an another probabilistic condition that is equilvalent to RH with probability one.[1] It has some suppositions which square-free numbers are random sequences and independent events with symmetrical distribution. In other words if a square-free number is taken at random and has an equal probability of containing an odd or an even number of distinct prime divisors,  $M(x) = O(x^{1/2+\varepsilon})$  and the RH is true with probability one. From corollary (3.1) and (3.2), we can verify a fact that  $Pr(\mu(n) = +1)$  and  $Pr(\mu(n) = -1)$  are equal. These are providing the plausible evidences for the Riemann Hypothesis.

# 4. A Proof of Riemann's Hypothesis

Theorem 4.1.

All non-trivial zeros of  $\zeta(s)$  have real part one-half.

Proof.

Using theorem (2.1), 
$$\lim_{x\to\infty} M(x) = 0$$

$$\lim_{x \to \infty} \frac{M(x)}{x^{1/2 + \varepsilon}} = 0, \text{ for every } \varepsilon > 0$$

This condition is equivalent to the Riemann hypothesis.[1]

Therefore, the Riemann hypothesis is true.

A PROOF OF RIEMANN HYPOTHESIS USING THE GROWTH OF MERTENS FUNCTION  $M(x\bar{y})$ 

## 5. CONCLUSION

I very simply prove the RH using the growth of M(x) approaches zero as  $x \to \infty$ . From now on, Riemann hypothesis is not his hypothesis any longer. It is reborn an obvious theorem.

The M(x) closely linked with the positions of zeroes of  $\zeta(s)$  have some questions still. Their relation has been very known that the RH is equivalent to  $M(x) = O(x^{1/2+\varepsilon})$ .[2, 4] I think that this relation is very similar to  $|\pi(x) - Li(x)| = O(\sqrt{x \log x})$  called Koch's result. RH is proven using the growth of M(x) approaches zero as  $x \to \infty$ . This condition is fairly stronger than  $O(x^{1/2+\varepsilon})$ . If Koch's result and M(x) are closely related, I conjecture that  $\lim_{x\to\infty} |\pi(x) - Li(x)| = 0$  alike the growth of M(x).

### Conjecture 1.

$$|Li(x) - \pi(x)| < C\sqrt{x} \log x$$
, where  $C \ge 0$ 

$$\lim_{x\to\infty}C=0$$

Today, the precise version of Koch's result is that  $|Li(x) - \pi(x)| < \pi/8\sqrt{x} \log x$ where x > 2657 proven by Schoenfeld.
