# Calculation of the Standard Model parameters and particles based on a SU(4) preon model 

Jan Helm<br>Technical University Berlin<br>Email: jan.helm@alumni.tu-berlin.de

#### Abstract

This paper describes an extension and a new foundation of the Standard Model of particle physics based on a $\mathrm{SU}(4)$-force called hyper-color. The hyper-color force is a generalization of the $\mathrm{SU}(2)$-based weak interaction and the $\mathrm{SU}(1)$-based right-chiral self-interaction, in which the W - and the Z-bosons are Yukawa residual-fieldcarriers of the hyper-color force, in the same sense as the pions are the residual-field-carriers of the color $\mathrm{SU}(3)$ interaction. Using the method of numerical minimization of the $\mathrm{SU}(4)$-Lagrangian based on this model, the masses and the inner structure of leptons, quarks and weak bosons are calculated: the mass results are very close to the experimental values. We calculate also precisely the value of the Cabibbo angle, so the mixing matrices of the Standard model, CKM matrix for quarks and PMNS matrix for neutrinos can also be calculated. In total, we reduce the 28 parameters of the Standard Model to 2 masses and 2 parameters of the hyper-color coupling constant.

1. $\mathrm{SU}(4)$ gauge theory
2. The Standard Model and QCD, the SU(4)-preon model and QHCD
3. The calculation method for the $\mathrm{SU}(4)$-preon model
4. The particles and families of the $\operatorname{SU}(4)$-preon model

5 , Weak hadron decays in the $\operatorname{SU}(4)$-preon model

## 1. $\mathrm{SU}(4)$ gauge theory

## Gauge theory

In the following, we consider the gauge theory QCD (quantum chromodynamics) based on $\mathrm{SU}(3)$ and the gauge theory QHCD (quantum hyper-color dynamics) based on $\mathrm{SU}(4)$.
The gauge invariant QCD Lagrangian is ( $\hbar=c=1$ )
$L=\bar{\psi}\left(i \gamma^{\mu} D_{\mu}-m\right) \psi-\frac{1}{4} G^{a}{ }_{\mu \nu} G_{a}{ }^{\mu \nu}$
where $\psi_{i}(x)_{\text {is the quark field, a dynamical function of spacetime, in the fundamental representation of the }}$ $\mathrm{SU}(3)$ gauge group, indexed by $i, j, \ldots ; \mathcal{A}_{\mu}^{a}(x)$ are the fields, also dynamical functions of spacetime, in the adjoint representation of the $\mathrm{SU}(3)$ or the $\mathrm{SU}(4)$ gauge group, indexed by $a, b, \ldots$ The $\gamma^{\mu}$ are Dirac matrices connecting the spinor representation to the vector representation of the Lorentz group.
The total field is $A_{\mu}(x) \equiv A_{\mu}^{a}(x) \cdot \lambda_{a} / 2$; and the Dirac-conjugate $\bar{\psi}_{i}(x)=\psi_{i}{ }^{c}(x) \gamma^{0}$, where $\psi_{i}{ }^{c}$ is the complex-conjugate.
$D_{\mu}$ is the gauge covariant derivative

$$
D_{\mu}:=\partial_{\mu}-i g A_{\mu}^{\alpha} \lambda_{\alpha}
$$

where is the coupling constant.
For the QCD based on $\mathrm{SU}(3), A_{\mu}{ }^{a}(x)$ is the (color) gluon gauge field, for eight different gluons is a fourcomponent Dirac spinor, and where is one of the eight Gell-Mann matrices, $A_{\mu}{ }^{a}(x)$ is the hc-boson field, for 15 hc-bosons and are the 15 generators of the $\mathrm{SU}(4)$,

$$

& 0
\end{aligned} 0
$$

The $\lambda_{\mu}$ matrices are orthogonal under trace $\operatorname{Tr}()$ and satisfy

$$
\operatorname{Tr}\left(\lambda_{\mu}\right)^{2}=2 ; \quad \mu=1 \cdots 15
$$

The symbol $G_{\mu u}^{a}$ represents the gauge invariant field strength tensor, analogous to the electromagnetic field strength tensor, $F^{\mu \nu}$, in quantum electrodynamics. It is given by $G^{a}{ }_{\mu \nu}=\partial_{\mu} A^{a}{ }_{\nu}-\partial_{\nu} A^{a}{ }_{\mu}+g f^{a b c} A^{b}{ }_{\mu} A^{c}{ }_{\nu}$
where $f_{a b c}$ are the structure constants of $\mathrm{SU}(3)$ or $\mathrm{SU}(4)$ : the generators $T^{a}$ satisfy the commutator relations $\left[T^{a}, T^{b}\right]=i f^{a b c} T^{c}$

## Yang-Mills theory

Yang-Mills theories are a special example of gauge theory with a non-commutative symmetry group given by the Lagrangian [12]

$$
\mathcal{L}_{\mathrm{gf}}=-\frac{1}{2} \operatorname{Tr}\left(F^{2}\right)=-\frac{1}{4} F^{a \mu \nu} F_{\mu \nu}^{a}
$$

, where for QCD with $\mathrm{SU}(3) F=G^{a}{ }_{\mu \nu}$
with the generators of the Lie algebra, indexed by $a$, corresponding to the $F$-quantities (the curvature or fieldstrength form) satisfying

$$
\operatorname{Tr}\left(T^{a} T^{b}\right)=\frac{1}{2} \delta^{a b}, \quad\left[T^{a}, T^{b}\right]=i f^{a b c} T^{c}
$$

where the $f^{a b c}$ are structure constants of the Lie algebra, and the covariant derivative defined as

$$
D_{\mu}=I \partial_{\mu}-i g T^{a} A_{\mu}^{a}
$$

where $I$ is the identity matrix (matching the size of the generators), $A^{a}{ }_{\mu}$ is the vector potential, and $g$ is the coupling constant. In four dimensions, the coupling constant $g$ is a pure number and for a $\mathrm{SU}(N)$ group one has The relation

$$
F_{\mu \nu}^{a}=\partial_{\mu} A_{\nu}^{a}-\partial_{\nu} A_{\mu}^{a}+g f^{a b c} A_{\mu}^{b} A_{\nu}^{c}
$$

follows from the commutator for the covariant derivative $D_{\mu}$

$$
\left[D_{\mu}, D_{\nu}\right]=-i g T^{a} F_{\mu \nu}^{a}
$$

The field has the property of being self-interacting and equations of motion that one obtains are said to be semilinear, as nonlinearities are both with and without derivatives. This means that one can manage this theory only by perturbation theory, with small nonlinearities.
From the given Lagrangian one can derive the equations of motion given by

$$
\partial^{\mu} F_{\mu \nu}^{a}+g f^{a b c} A^{\mu b} F_{\mu \nu}^{c}=0
$$

(Yang-Mills-equations), which correspond to the Maxwell equations in electrodynamics, where $f^{a b c}=0$
Putting these can be rewritten as

$$
\left(D^{\mu} F_{\mu \nu}\right)^{a}=0
$$

The Bianchi identity holds

$$
\left(D_{\mu} F_{\nu \kappa}\right)^{a}+\left(D_{\kappa} F_{\mu \nu}\right)^{a}+\left(D_{\nu} F_{\kappa \mu}\right)^{a}=0
$$

which is equivalent to the Jacobi identity

$$
\left[D_{\mu},\left[D_{\nu}, D_{\kappa}\right]\right]+\left[D_{\kappa},\left[D_{\mu}, D_{\nu}\right]\right]+\left[D_{\nu},\left[D_{\kappa}, D_{\mu}\right]\right]=0 \quad \text { for Lie-groups }
$$

since Define the dual strength tensor $\tilde{F}^{\mu \nu}=\frac{1}{2} \varepsilon^{\mu \nu \rho \sigma} F_{\rho \sigma}$ then the Bianchi identity can be rewritten as $D_{\mu} \tilde{F}^{\mu \nu}=0$.

A source current $J^{a}{ }_{v}$ enters into the equations of motion (eom) as

$$
\partial^{\mu} F_{\mu \nu}^{a}+g f^{a b c} A^{b \mu} F_{\mu \nu}^{c}=-J_{\nu}^{a}
$$

The Dirac part of the Lagrangian is
$L_{D}=\bar{\psi}\left(i \hbar D_{\mu} \gamma^{\mu}-m c\right) \psi$
with the resulting eom=gauge Dirac equation
$\left(i \hbar D_{\mu} \gamma^{\mu}-m c\right) \psi=0$

## The running coupling constant of the QCD

With the potential
$V(r)=-\frac{4}{3} \frac{\alpha_{s} \hbar c}{r}+k r \quad$ potential $=\langle q \bar{q}\rangle$

The static qq potential in the quenched approximation obtained by the Wuppertal collaboration. The data at
$\beta=6.0,6.2,6.4$ and 6.8 has been scaled by $\mathrm{R}_{0}$, and normalized such that $\mathrm{V}\left(\mathrm{R}_{0}\right)=0$. The collapse of the different sets of data on to a single curve after the rescaling by $\mathrm{R}_{0}$ is evidence for scaling. The linear rise at large $r$ implies confinement. [9]

The color confinement results from $\lim (V(r), r \rightarrow \infty)=\infty$

## Callan-Symanzik equation

The Callan-Symanzik equation describes the behavior of the transfer function of a Feynman diagram with $n$ momentums [12]

$$
G^{(n)}\left(x_{1}, x_{2}, \ldots, x_{n} ; M, g\right)
$$

$$
\text { , where } \mathrm{M}=\text { energy and } \mathrm{g}=\text { coupling constant }
$$

$$
M \rightarrow M+\delta M
$$

under scaling transformation $g \rightarrow g+\delta g$
It has the form
$\left[M \frac{\partial}{\partial M}+\beta(g) \frac{\partial}{\partial g}+n \gamma\right] G^{(n)}\left(x_{1}, x_{2}, \ldots, x_{n} ; M, g\right)=0$ , where $\quad \gamma=-\frac{M}{\delta M} \delta \eta \quad \beta=\frac{M}{\delta M} \delta g$

From the definition and setting $\mu=M$, we get a differential equation for $\mathrm{g}(\mu)$ :
$\mu \frac{\partial g}{\partial \mu}+\beta(g)=0$
The running coupling for QCD is characterized by the $\beta$-function with colors $N=3$, flavors $n_{f}=3, \mu=\operatorname{transfer}$ energy

$$
\begin{aligned}
& \mu \frac{\partial g}{\partial \mu}=-\beta(g)=-\left(\beta_{0} g^{3}+\beta_{1} g^{5}+\ldots\right) \\
& \beta_{0}=\left(\frac{11 N-2 n_{f}}{3}\right) / 16 \pi^{2} \\
& \beta_{1}=\left(\frac{34 N^{2}}{3}-\frac{10 N n_{f}}{3}-\frac{n_{f}\left(N^{2}-1\right)}{N}\right) /\left(16 \pi^{2}\right)^{2} .
\end{aligned}
$$

resulting in $g(\mu)=\frac{1}{\sqrt{2 \beta_{0} \log \left(\frac{\mu}{\Lambda}\right)}}$ for $\mu \rightarrow \infty$
$\alpha_{s}(\mu)=\frac{g^{2}(\mu)}{4 \pi}=\frac{1}{8 \pi \beta_{0} \log \left(\frac{\mu}{\Lambda}\right)}=\frac{12 \pi}{\left(11 N-2 n_{f}\right) \log \left(\frac{\mu^{2}}{\Lambda^{2}}\right)} \quad \alpha$-coupling constant
where
$\Lambda \approx 220 \mathrm{MeV}$ critical energy of $\mathrm{QCD}, \Lambda \approx \mathrm{m}$ (pion) $3 / 2=210 \mathrm{MeV}$
$n_{F}=3$ : number of quark flavours
The corresponding critical length of QCD $r_{0 c}=\frac{\hbar c}{\Lambda}=\frac{1.96 * 10^{-7} \mathrm{eVm}}{220 \mathrm{MeV}}=0.89 * 10^{-15} \mathrm{~m}$
which about the proton radius.
For energies $\mu \approx \Lambda$ it must be modified to avoid the singularity
$g_{c}(\mu)=4 \pi \sqrt{\frac{3}{54 \sqrt{\left(\log \left(\frac{\mu}{\Lambda}\right)\right)^{2}+c_{G E 0}^{2}}}}$, for the numerical calculation we set $c_{G E 0}=\frac{1}{\log \left(\frac{m(p)}{\Lambda_{Q C D}}\right)}=0.683 \approx \log 2$,
which is consistent with the Callan-Symanzik relation for $\mu>2 \Lambda$, as shown below

$g_{c}(\mu), \mu$ in $E_{0}$-units, $E_{0}=196 \mathrm{MeV}$

## The running coupling constant of the QHCD

For the QHCD the Callan-Symanzik equation is still valid, as it is derived from the scale-independence of the theory.
The running coupling for QHCD with colors $N=4$, flavors $n_{f}=3$, $\mu=$ transfer energy becomes
$\alpha_{h c}(\mu)=\frac{g^{2}(\mu)}{4 \pi}=\frac{12 \pi}{\left(11 N-2 n_{f}\right) \log \left(\frac{\mu^{2}}{\Lambda_{h c}{ }^{2}}\right)}$
Again, it must be corrected to avoid a singularity for $\mu=\Lambda_{h c}$
$g_{h c}(\mu)=4 \pi \sqrt{\frac{3}{54 \sqrt{\left(\log \left(\frac{\mu}{\Lambda_{h c}}\right)\right)^{2}+c_{G E 1}{ }^{2}}}}$
we set $\Lambda_{h c}=2 m\left(Z_{0}\right)=180 \mathrm{GeV}$ in analogy to the QCD , and $c_{G E 1}=\frac{1}{\log \left(\frac{m(t)}{m(d)}\right)}$, with the masses of the top-
and the d-quark: this should assess the logarithmic scale of the generation energy ratio.
Both settings are of course only a plausible guess, but these values work very well for the preon model, as we will see.
The coupling constant $g_{h c}$ for the QHCD is shown below (energy in $1000 E_{\sigma}$-units):

The peak is much higher than in QCD, which reflects the enormous span of the mass scale in the Standard Model.

The corresponding critical length of QHCD $r_{0 h c}=\frac{\hbar c}{\Lambda_{h c}}=\frac{1.96 * 10^{-7} \mathrm{eVm}}{180 \mathrm{GeV}}=1.08 * 10^{-18} \mathrm{~m}$
which is about $1 / 1000$ of the proton radius: the energy scale of the QHCD is by a factor 1000 larger, and consequently the length scale by a factor 1000 smaller than in QCD. This agrees with the experimental assessment of the quark radius being about $1 / 1000$ of the proton radius.
2. The Standard Model and QCD, the $S U(4)$-preon model and QHCD

### 2.1 Parameters of the Standard Model

Basic particles of the standard model [20]

## Fermions in the Standard Model

The following table describes the basic fermion particle of the SM

| Generation 1 |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\underset{\text { (left-handed) }}{\text { Fermion }}$ | Symbol | Electric charge | Weak isospin | Weak hypercharge | Color charge * | Mass ** |
| Electron | $e^{-}$ | -1 | $-1 / 2$ |  | 1 | 511 keV |
| Positron | $e^{+}$ | +1 | 0 |  | 1 | 511 keV |
| Electron neutrino | $\nu_{e}$ | 0 | +1/2 | -1 | 1 | $<0.28 \mathrm{eV}^{* * * *}$ |
| Electron antineutrino | $\bar{\nu}_{e}$ | 0 | 0 | 0 | 1 | $<0.28 \mathrm{eV}^{* * * *}$ |
| Up quark | $u$ | $+2 / 3$ | +1/2 | +1/3 | 3 | $\sim 3 \mathrm{MeV}$ *** |
| Up antiquark | $\bar{u}$ | $-2 / 3$ | 0 | $-4 / 3$ | $\overline{3}$ | $\sim 3 \mathrm{MeV}$ *** |
| Down quark | $d$ | $-1 / 3$ | $-1 / 2$ | +1/3 | 3 | $\sim 6 \mathrm{MeV}$ *** |
| Down antiquark | $\bar{d}$ | +1/3 | 0 | $+2 / 3$ | $\overline{3}$ | $\sim 6 \mathrm{MeV}$ *** |

## Generation 2

| Fermion (left-handed) | Symbol | Electric charge | Weak isospin | Weak hypercharge | Color <br> charge * | Mass ** |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Muon | $\mu^{-}$ | -1 | $-1 / 2$ | -1 | 1 | 106 MeV |
| Antimuon | $\mu^{+}$ | +1 | 0 | +2 | 1 | 106 MeV |
| Muon neutrino | $\nu_{\mu}$ | 0 | +1/2 |  | 1 | $<0.28 \mathrm{eV}$ **** |
| Muon antineutrino | $\bar{\nu}_{\mu}$ | 0 | 0 | 0 | 1 | $<0.28 \mathrm{eV}$ **** |
| Charm quark | $c$ | +2/3 | +1/2 | $2+1 / 3$ | 3 | $\sim 1.337 \mathrm{GeV}$ |
| Charm antiquark | $\bar{c}$ | $-2 / 3$ | 0 | $-4 / 3$ | $\overline{3}$ | $\sim 1.3 \mathrm{GeV}$ |
| Strange quark | $s$ | $-1 / 3$ | $-1 / 2$ | $2+1 / 3$ | 3 | $\sim 100 \mathrm{MeV}$ |
| Strange antiquark | $\bar{s}$ | +1/3 | 0 | +2/3 | $\overline{3}$ | $\sim 100 \mathrm{MeV}$ |

## Generation 3

| Top quark | $t$ | +2/3 | $+1 /$ | $+1 / 3$ | 3 | 171 GeV |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Top antiquark | $\bar{t}$ | $-2 / 3$ | 0 | $-4 / 3$ | $\overline{3}$ | 171 GeV |
| Bottom quark | $b$ | $-1 / 3$ | $-1 /$ | $+1 / 3$ | 3 | $\sim 4.2 \mathrm{GeV}$ |
| Bottom antiquark | $\bar{b}$ | +1/3 | 0 | +2/3 | $\overline{3}$ | $\sim 4.2 \mathrm{GeV}$ |

The quark radius: as of 2014, experimental evidence indicates they are no bigger than $10^{-4}$ times the size of a proton, i.e. less than $10^{-19}$ metres [16]

## Field bosons

The following table describes the basic bosons of the SM : 3 massive bosons $\mathrm{W} \pm, \mathrm{Z}, \mathrm{H}$ and 2 massless fieldcarriers : photon $\gamma$ and gluon $g$.

| Particle | Charge | w.Isospin T | w.hcharge Y | Spin | Color | Lifetime | Mass |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{W} \pm$ | $\pm 1$ | $\pm 1$ | 0 | 1 | 0 | $3^{*} 10^{-25} \mathrm{~s}$ | 80.4 GeV |
| Z | 0 | 0 | 0 | 1 | 0 | $3^{*} 10^{-25} \mathrm{~s}$ | 91.2 GeV |
| $\gamma$ photon | 0 | 0 | 0 | 1 | 0 |  | 0 |
| g gluon | 0 | 0 | 0 | 1 | 3 |  | 0 |
| H higgs | 0 | 0 | 0 | 0 | 0 | $10^{-22} \mathrm{~s}$ | 125.1 GeV |

Parameters Standard model [9]

### 2.2 The basics of the preon model

The preon model describes the basic particles of the Standard Model (leptons, quarks and exchange bosons) as composed of smaller particles (preons), which obey a super-strong hyper-color interaction.
Examples are the rishon model (Harari 1979 [26], [27]) and the primon model (de Souza 2002 [25]) .

## The rishon model

In the rishon model, there are two preons (called rishons) T (charge $+1 / 3 \mathrm{e}$ ) and V (charge 0 ). Leptons and quarks and exchange bosons are built of 3 rishons. They obey a hc-interaction based on $\mathrm{SU}(3)$, the 3 -rishon combinations have the (color) x (hyper-color) representation $\mathrm{SU}(3)_{\mathrm{c}} \mathrm{xSU}(3)_{\mathrm{hc}}$
TTT $=$ antielectron
VVV = electron neutrino
TTV, TVT and VTT $=$ three colours of up quarks
TVV, VTV and VVT = three colours of down antiquarks
TTT = electron
VVV = electron antineutrino
TTV, TVT, VTT = three colours of up antiquarks
TVV, VTV, VVT $=$ three colours of down quarks
$\mathrm{W}^{+}$boson = TTTVVV
Generations are explained as excited states of the first generations, mass is not explained.

## The primon model

In the primon model there are four preons (called primons) ( $\mathrm{p}_{1}, \mathrm{p}_{2}, \mathrm{p}_{3}, \mathrm{p}_{4}$ ), which carry charge ( $+5 / 6,-1 / 6,-1 / 6,-1 / 6$ ) and hc-charge, they obey a hc-interaction based on $\operatorname{SU}(2)$.
Quarks are built of two primons:
$\mathrm{u}\left(\mathrm{p}_{1}, \mathrm{p}_{2}\right), \mathrm{c}\left(\mathrm{p}_{1}, \mathrm{p}_{3}\right), \mathrm{t}\left(\mathrm{p}_{1}, \mathrm{p}_{4}\right), \mathrm{d}\left(\mathrm{p}_{2}, \mathrm{p}_{3}\right), \mathrm{s}\left(\mathrm{p}_{2}, \mathrm{p}_{4}\right), \mathrm{b}\left(\mathrm{p}_{3}, \mathrm{p}_{4}\right)$,
leptons are non-composite, there are 3 non-composite Higgs-bosons.
Generations are explained as primon-configuration, the mass spectrum is only qualitatively explained

## Requirements for the preon model

The two basic ideas of the preon model (PM) are
-the basic particles of the Standard Model (SM) are composed of a few fundamental fermions
-there is a super-strong hyper-color interaction, with massless field bosons
A successful PM should uphold the symmetries and invariances of the SM and solve its main problems:
-PM should encompass the preservation of the baryon and lepton number
-PM should explain and derive the generations (flavor) of the SM and their energy scales
-PM should explain the allowed and not-allowed decay modes and the flavor-mixing of the SM
-PM should correctly calculate the mass spectrum, and explain the huge difference in mass scale between leptons and quarks, and between the generations: m (neutrino $\left.v_{\mathrm{e}}\right) \sim 10^{-4} \mathrm{eV},: \mathrm{m}$ (top quark t ) $=170 \mathrm{GeV}$, which makes a factor of $10^{15}$
-PM should describe the weak exchange bosons $\mathrm{W}, \mathrm{Z}$, and the higgs H as Yukawa-bosons of the hc-interaction, as all other fundamental field bosons graviton $A^{\mu \nu}$, photon $A^{\mu}$, gluon $A_{c}{ }^{\mu}$ are massless waves; the field bosons $\mathrm{A}_{\mathrm{hc}}{ }^{\mu}$ of hc should be also massless
-hc interaction should be stronger the $\mathrm{SU}(3)$-color interaction and should encompass the weak $\mathrm{SU}(2)$, also it should reproduce the spontaneous symmetry breaking of the electroweak symmetry group $S U(2)_{\mathrm{L}, \text { weak }} \otimes \mathrm{SU}(1)_{\mathrm{R}, \text { weak }} \otimes \mathrm{SU}(1)_{\text {em }}$ with their exchange bosons $\left\{\mathrm{W}^{\mu}, Z^{\mu}\right\} \otimes\left\{Z^{\mu}\right\} \otimes\left\{A^{\mu}\right\}$
-PM should reduce the 28 parameters of the SM to very few fundamental parameters

### 2.3 Realization of the $S U(4)$ preon model

The $\mathrm{SU}(4)$ preon model (SU4PM) is based essentially on two assumptions
-The SU4PM postulates two basic Weyl-spinors $\{\mathrm{r}, \mathrm{q}\}$ as the fundamental particles and the $\mathrm{SU}(4)$ as the gauge group of the hc-interaction, with spin $S=1 / 2$, with electrical charge $\mathrm{Q}_{\mathrm{e}}=\{-1 / 2,1 / 6\}$ and color charge $\mathrm{Q}_{\mathrm{c}}=\{0,1\}$ -The field-bosons are the 15 generators $\mathrm{A}_{\mathrm{hc}}{ }^{\mu}$ of the $\mathrm{SU}(4)$, described by the 15 standard generator $4 \times 4$ matrices $\lambda_{i}$ of the $\operatorname{SU}(4)$. The $\mathrm{SU}(4)$ has 4 hc-charges: \{chirality L, chirality R , electrical charge + , electrical charge - \} in analogy to the 3 color charges of the $S U(3):\{r, g, b\}$.

From these assumptions follow the basic particle families of
-leptons $\mathrm{L}=\mathrm{r} \otimes \mathrm{r}$ being a hc-tetra-spinor of a doublet of two r-preons, fermions with total spin $\mathrm{S}=1 / 2$
-quarks $\mathrm{Q}=\mathrm{r} \otimes \mathrm{q}$ being a hc-tetra-spinor of a doublet of an r - and a q -preon, colored fermions with color $\mathrm{Q}_{\mathrm{c}}=1$ with total spin $\mathrm{S}=1 / 2$
-(hypothetical) strong neutrinos $\mathrm{N}_{\mathrm{c}}=\mathrm{q} \otimes \mathrm{q}$ being a hc-tetra-spinor of a doublet of two q-preons, colored fermions with color $\mathrm{Q}_{\mathrm{c}}=0$ with total spin $\mathrm{S}=1 / 2$
-weak bosons $\mathrm{B}_{\mathrm{w}}=\mathrm{r} \pm \mathrm{r}$ being a linear combinations of two or more r -preons, with total spin $\mathrm{S}=0$ (scalar like higgs $H$ ) or $S=1$ (vector like $W$ and $Z$ )
-(hypothetical) strong bosons $\mathrm{B}_{\mathrm{c}}=\mathrm{q} \pm \mathrm{q}$ being a linear combinations of two or more q -preons, with color $\mathrm{Q}_{\mathrm{c}}=0$ and total spin $\mathrm{S}=0$ (scalar like higgs $\mathrm{H}_{\mathrm{q}}$ ) or $\mathrm{S}=1$ (vector like $\mathrm{Z}_{\mathrm{q}}$ )

A a hc-tetra-spinor is a hc-quadruplet with the hc-charges $\{\mathrm{L}-, \mathrm{L}+, \mathrm{R}-, \mathrm{R}+\}$.
Both preons can carry all four charges of $\operatorname{SU}(4)$, i.e. there are $\{r L-, r L+, r R-, r R+\}$ and $\{q L-, q L+, q R-, q R+\}$, where the spinor-anti-spinor pairs are $\{\mathrm{rL}-, \mathrm{rR}+\}$ and $\{\mathrm{rL}+, \mathrm{rR}-\}$.
The r-q-doublets, i.e. the quarks, have one more degree of freedom, as they consist of different fermions, and are therefore chiral-neutral, which is energetically more favorable.

A hc-doublet occupies two positions in a hc-tetra-spinor with indices ( $\mathrm{i}, \mathrm{j}$ ), e.g the e-neutrino with the configuration $\{\mathrm{rL}-, \mathrm{rL}+, 0,0\}$ has the hc-indices $(1, \overline{2})$, the bar over 2 signifies the anti-spinor.
One can show, that for two hc-indices $\{\mathrm{i}, \mathrm{j}\}$ there are three field-boson configurations, which are compatible with the $\mathrm{SU}(4)$ symmetry: one boson $A_{i j}$ (corresponding to the non-diagonal hc-matrix $\tilde{\lambda}_{i j}$ interchanging $i$ with $j$, e.g. for $(i, j)=(1,2) \quad \tilde{\lambda}_{i j}=\lambda_{1}$ ), four bosons $A_{i j}, \bar{A}_{i j}, A_{k l}, \bar{A}_{k l}$ (interchanging resp. $(i, j),(i, \bar{j})$, and the dual index pairs $(k, l),(k, \bar{l})$ ), and all 15 bosons as the third configuration. These correspond to the three generations (flavors) of the SM, as the calculation shows.

## Basic parameters of SU4PM

We have 4 parameters for SU4PM: 2 preon masses, and for the coupling constant the critical energy $\Lambda_{h c}$ and the peak height constant $c_{G E 1}$ The 2 parameters of the coupling constant have been derived in chap. 1 . For the mass of the r-preon, we make a guess of m (e-neutrino) $/ 3$ : in the lightest lepton, the e-neutrino, there are two $r$-preons and one hc-boson, so $m(r)$ will be approximately $1 / 3$ of the assessed $m$ (e-neutrino): this is assumed to be $1 / 1000(1000=$ approximate factor for flavor 3$)$ of the best upper limit for $m(t a u-n e u t r i n o)=0.1 \mathrm{eV}$. For the mass of the $q$-preon, we take $1 / 3$ of mass(u-quark) the lightest quark, in analogy to the $r$-preon.

## preon data

r-preons \{rL-,rL+,rR-,rR+\}
$\mathrm{Q}(\mathrm{r})=-1 / 2, \mathrm{~m}(\mathrm{r})=0.033 \mathrm{meV}$
q-preons $\{q \mathrm{qL}-, \mathrm{qL}+, \mathrm{qR}-, \mathrm{qR}+\}$
$\mathrm{Q}(\mathrm{q})=+1 / 6, \mathrm{~m}(\mathrm{q})=0.77 \mathrm{MeV}$
coupling constant of hc-interaction
The coupling from the Callan-Symanzik equation must be corrected to avoid a singularity for $\mu=\Lambda_{h c}$
$g_{h c}(\mu)=4 \pi \sqrt{\frac{3}{54 \sqrt{\left(\log \left(\frac{\mu}{\Lambda_{h c}}\right)\right)^{2}+c_{G E 1}{ }^{2}}}}$
we set $\Lambda_{h c}=2 m\left(Z_{0}\right)=180 \mathrm{GeV}$ in analogy to the QCD , and $c_{G E 1}=\frac{1}{\log \left(\frac{m(t)}{m(d)}\right)}=0.095$

## The configuration of the SM in the SU4PM

Every basic particle of the SM is assigned a preon and a hc-boson configuration.
The preon configuration of a fermion (leptons and quarks) occupies two of the 4 positions in a hc-quadruplet by a Dirac-bispinor, e.g. for electron with index pair (1,3) we have $\binom{r L^{-}}{0}$ in position 1 and $\binom{r R-}{0}$ in position 3, according to the hc-charge. The hc-quadruplet has the hc-charges (L-, L+, R-, R+) .
There are 3 possible hc-boson configurations for an index-pair $(i, j)$, which are consistent with the $\mathrm{SU}(4)$ symmetry: 1 hc -boson Aij corresponding to first generation of flavor=1, 4 hc-bosons $A i j+\bar{A} i j+A k l+\bar{A} k l$ corresponding to flavor $=2$ (the bar specifies the conjugate coupler, and $(k, l)$ is the complementary index pair, e.g. for electron it is $(2,4)$ ), and finally all 15 hc-bosons corresponding to flavor=3 .

The fermions (leptons and quarks) have two independent preon-components $u 1$ and $u 2$, they form a bispinor with spin $S=1 / 2$.
The bosons (weak boson $\mathrm{W}, \mathrm{Z}, \mathrm{H}$ ) have only one independent preon-component u , which is a linear combination of two preons, the spins add up to $\mathrm{S}=1$ for W and Z , or to $\mathrm{S}=0$ for H , e.g. for $\mathrm{Z}=\mathrm{Z} 0$
$u 1=((r L-)+(r R-)) / \sqrt{2}$ and $Z 0=\left(\binom{u 1}{0},\binom{0}{u 1},\binom{u 1}{0},\binom{0}{u 1}\right) / \sqrt{2}$. The weak bosons W and Z0 are carrier of the residual weak interaction, and the higgs H generates masses for all r-containing particles: leptons, quarks , weak bosons and the r-preon itself.
The SU4PM predicts the existence of hypothetical strong neutrinos, which consist of $q \bar{q}$ with electrical charge $\mathrm{Q}=0$ and color charge $\mathrm{Q}_{\mathrm{c}}=0$. They are heavy $(\mathrm{m}(\mathrm{qnu})=23.2 \mathrm{MeV})$ practically non-interacting particles: the interact only via very heavy q-boson $\mathrm{Zq}(\mathrm{m}(\mathrm{Zq})=644 \mathrm{GeV}))$, i.e. they interact only at high resonance energies with small cross-sections. There is a new hypothetical model for Dark Matter called SIMP with mass around 100 MeV and interacting strongly at high resonance energies [28]. The strong-neutrinos do fit into this category. Furthermore, the SU4PM predicts the existence of strong bosons Zq and Hq , in analogy to weak bosons $\mathrm{Z0}$ and H , built of q -preons instead of r-preons. the strong neutrinos interact with themselves via Zq , and Hq generates masses for strong neutrinos and the q-preon.
The decay of neutron and pion requires (to safeguard the conservation of hc-charge) the existence of further weak neutrinos: the non-chiral (sterile) neutrinos with masses similar to lepton neutrinos. The nc-neutrinos are neutral , non-chiral, and interact with themselves and lepton neutrinos via the weak ZL-boson similar to the Z0, but left-chiral.

## 3. The calculation method of the $\mathrm{SU}(4)$-preon model

We apply for the calculation of the parameters of SM particles the numerical minimization of action, using a Ritz.Galerkin expansion for the hc-bosons and a parameterized gaussian for the preons.

### 3.1 The ansatz for the wavefunction

## He-boson wavefunction

For the hc-boson wavefunction we apply here the full Ritz-Galerkin series on the function system $f_{k}(r, \theta)=\left\{\right.$ bfunc $\left.\left(r, r_{0}, d r_{0}\right) r^{k_{1}}, k_{1}=0, \ldots, n_{r}\right\} \times\left\{\left(\cos ^{k_{2}} \theta, \cos ^{k_{2}} \theta \sin \theta\right), k_{2}=0, \ldots, n_{\theta}\right\}$ with coefficients $\alpha_{k}$, where $\operatorname{bfunc}\left(r, r_{0}, d r_{0}\right)=\frac{1}{1+\exp \left(\frac{r-r_{0}}{d r_{0}}\right)}$ is a Fermi-step-function which limits the region $r \leq r_{0}$ of the preon with „smearing width" $d r_{0}$.
$A g(t, r, \theta)=\left\{\left(\begin{array}{l}A g_{i 1}(t, r, \theta) \cos a A_{i} \\ A g_{i 2}(t, r, \theta) \cos a A_{i} \\ A g_{i 1}(t, r, \theta) \sin a A_{i} \\ A g_{i 2}(t, r, \theta) \sin a A_{i}\end{array}\right\}, i=1, \ldots, 15\right\}$, where $a A_{i}$ is the phase angle between the particle and the anti-particle part of the hc-boson, and with the Ritz-Galerkin-expansion
$A g_{k l}(t, r, \theta)=\sum_{j} \alpha[k, l, j] f_{j}(r, \theta) \exp \left(-i t E A_{k}\right)$ with energies $E A_{k}$
$k=1 . . .15, l=1,2$
Because of hc-symmetry, the active (non-zero) hc-bosons are
$A g=\left\{A g_{1}, \ldots, A g_{15}\right\}$ all hc-bosons: generation 3, flavor=3
$A g=\left\{A g_{i j}, \bar{A} g_{i j}, A g_{k l}, \bar{A} g_{k l}\right\} 4$ hc-bosons: coupler and anti-coupler for hc-indices (i,j) and the corresponding 2 coupler-anti-coupler pair for the complementary indices (k,l): generation 2, flavor=2
$A g=\left\{A g_{i j}\right\}$ one hc-boson for the hc-indices (i, j ): generation 1, flavor=1.

## Particle wavefunction

The hc-quadruplet has 4 positions with the hc-charges $\{\mathrm{L}-, \mathrm{L}+, \mathrm{R}-, \mathrm{R}+\}$, and the particle wavefunction of a fermion (lepton or quark) has two positions occupied with indices (i,j)
$u=\left\{. .\left(p_{1}\right) \ldots\left(p_{2}\right) \ldots\right\} \quad p_{1}$ and $p_{2}$ are Weyl spinors with 2 components.
For the preons we use here a model of a gaussian "blob"
$p_{k}(t, r, \theta)=\binom{\exp \left(-\right.$ it $\left.E u_{k}\right) \exp \left(-\frac{\left(\vec{r}-\vec{r}_{u, k}\right)^{2}}{2 d r_{u, k}}\right) \cos a_{k}}{\exp \left(-\right.$ it $\left.E u_{k}\right) \exp \left(-\frac{\left(\vec{r}-\vec{r}_{u, k}\right)^{2}}{2 d r_{u, k}}\right) \sin a_{k}}$
,where $E u_{k}$ is the energy, $\vec{r}_{u, k}=\left(r u_{k}, \theta u_{k}\right)$ and $d r_{u, k}$ is the
position $(r, \theta)$ and its width, $a_{k}$ is a phase .

### 3.2 The numerical algorithm [24]

The energy, length, and time are made dimensionsless by using the units: $\mathrm{E}\left(E_{0}=\frac{\hbar c}{1 a m}=0.196 \mathrm{TeV}\right), \mathrm{r}(f m)$, $\mathrm{t}(\mathrm{am} / \mathrm{c}) \mathrm{am}=10^{-18} \mathrm{~m}$. We can assume axial symmetry, so we can set $\varphi=0$ and use the spherical coordinates $(t, r, \theta)$.
We choose the equidistant lattice for the intervals $(t, r, \theta) \in[0,1] \times[0,1] \times[0, \pi]$ with $21 \times 21 \times 11$ points and, for the minimization 8 x in parallel, 8 random sublattices :
$l[i x, j]=\left\{\left\{\left(t_{i 1}, r_{i 2}, t_{i 3}\right) \mid(i 1, i 2, i 3)=\right.\right.$ random $($ lattice,$\left.\left.j=1 \ldots 100)\right\} \mid i x=1, \ldots, 8\right\}$.
For the Ritz-Galerkin expansion we use the 12 functions
$f_{k}(r, \theta)=\left\{b f u n c\left(r, r_{0}, d r_{0}\right) r^{k_{1}}, k_{1}=0, \ldots, n_{r}\right\} \times\left\{\left(\cos ^{k_{2}} \theta, \cos ^{k_{2}} \theta \sin \theta\right), k_{2}=0, \ldots, n_{\theta}\right\}$
The action $S=\int L_{Q H C D}\left(x^{\mu}, q_{i}, A g_{i}\right) r^{2} \sin \theta d t d r d \theta d \varphi$ becomes a mean-value on the sublattice $l[i x]$
$\tilde{S}[i x]=\frac{1}{N(l[i x])} \sum_{x \in[i x]_{\operatorname{stb}}} L_{\text {QHCD }}\left(x, q_{i}, A g_{i}\right) 2 \pi V_{t r \theta}$, where $V_{t r \theta}=\pi$ the $(t, r, \theta)$-volume and $N(l[i x])$ is the number of points. We set $N(l[i x])=100$ for generation 1 and $2, N(l[i x])=25$ for generation 3 .
We impose the boundary condition for $A g_{i}\left(r=r_{0}\right)=0$ via penalty-function (imposing exact conditions is possible, but slows down the minimization process enormously).
$\tilde{S}$ is minimized 8 x in parallel with the Mathematica-minimization method "simulated annealing".
The proper parameters of the preons and the hc-bosons are:
$\operatorname{par}\left(p_{i}\right)=\left\{E u_{i}, a_{i}, r u_{i}, \theta u_{i}, d r u_{i}\right\}, \operatorname{par}\left(A g_{i}\right)=\left\{E A_{i}, a A_{i}\right\}$
The complexities and execution times (on a 2.7 GHz Xeon E5 work-station) differ greatly for different generations.
For the generation 1 electron $e=\left(\binom{r L-}{0}, 0,\binom{r R-}{0}, 0\right)$ with 1 hc boson A13:
complexity (Lagrangian) $=6.2 * 10^{6}$ terms, minimization time $\mathrm{t}($ minimization $)=37 \mathrm{~s}$.
For the generation 3 tauon $\tau=\left(\binom{r L-}{0}, 0,\binom{r R-}{0}, 0\right)$ with all 15 hc-bosons:
complexity (Lagrangian $)=283 * 10^{6}$ terms, minimization time $\mathrm{t}($ minimization $)=2500 \mathrm{~s}$.

## 4. The particles and families of the $\mathbf{S U}(4)$-preon model

Here we present the result of the calculation of the masses, inner structure, and some of the angles of the mixing matrices CKM and PMNS, using the minimization of the action described in chapter 3.

### 4.1 Charged leptons electron, muon, tau

Spin $S=1 / 2$, two free preons, occupying fixed positions in the hc-tetra-spinor
Preon configuration: $u=\left(\binom{r L-}{0}, 0,\binom{r R-}{0}, 0\right)$
Boson configuration: flavor=1: $(A 13=\lambda 4)$, flavor=2: $(A 13=\lambda 4, \bar{A} 13=\lambda 5, A 24=\lambda 11, \bar{A} 24=\lambda 12)$
flavor=3: all 15 bosons
The leptons are charged particles, they interact electromagnetically or weakly via Z and W bosons.
The leptons are spherically symmetric, and have therefore the gyromagnetic ratio $\mathrm{g}=2$ exactly, which is valid from the Dirac-equation for a point-like (or spherically symmetric) spin- $1 / 2$-particle. The spherical symmetry arises from the fact, that all leptons consist of two r-preons, which differ only in the hc-charge, so it is plausible that their geometric parameters are equal (equal radius $r_{i}$, its uncertainty $\mathrm{dr}_{\mathrm{i}}$, equal phase angle $\mathrm{a}_{\mathrm{i}}$, and inter-preon-angle th=0).

Ai(tau)

### 4.2 Lepton neutrinos $v_{e}, v_{m u}, v_{\text {tau }}$

Spin $S=1 / 2$, two free preons, occupying fixed positions in the hc-tetra-spinor
Preon configuration: $u=\left(\binom{r L-}{0},\binom{0}{r L+}, 0,0\right)$
Boson configuration: flavor=1: $(A 12=\lambda 1)$, flavor $=2:(A 12=\lambda 1, \bar{A} 12=\lambda 2, A 34=\lambda 13, \bar{A} 34=\lambda 14)$
flavor=3: all 15 bosons
The lepton neutrinos are spherically symmetric, as shown in the calculation, and have therefore zero magnetic momentum. The spherical symmetry arises from the fact, that all leptons consist of two r-preons, which differ only in the hc-charge, so it is plausible that their geometric parameters are equal (equal radius $\mathrm{r}_{\mathrm{i}}$, its uncertainty $d_{i}$, equal phase angle $a_{i}$, and inter-preon-angle th=0).
The lepton neutrinos are neutral, interact only weak via Z and W bosons.

4.3 Non-chiral sterile (hypothetical) neutrinos vs1, vs2, vs3

Spin $S=1 / 2$, two free preons, occupying fixed positions in the hc-tetra-spinor
Preon configuration: $u=\left(\binom{r L-}{0}, 0,0,\binom{0}{r R+}\right)$
Boson configuration: flavor=1: $(A 14=\lambda 9)$, flavor $=2:(A 14=\lambda 9, \bar{A} 14=\lambda 10, A 23=\lambda 6, \bar{A} 23=\lambda 7)$
flavor=3: all 15 bosons
The hypothetical sterile neutrinos are involved in the neutron decay and interact only among themselves and with lepton neutrinos via the weak chiral boson ZL (see 4.1), so the denomination "sterile" is justified. They have similar masses as the lepton neutrinos, but are Majorana particles: antiparticle=particle. Like lepton neutrinos, they are spherically symmetric and have zero magnetic momentum.

### 4.4 U-quarks u, c, b

Spin $S=1 / 2$, two free preons, occupying fixed positions in the hc-tetra-spinor
Preon configuration: $u=\left(0,\binom{(r L++q L+) / \sqrt{2}}{(r L++q L+) / \sqrt{2}}, 0,\binom{(r R++q R+) / \sqrt{2}}{(r R++q R+) / \sqrt{2}}\right)$
Boson configuration: flavor=1: $(A 24=\lambda 11)$, flavor $=2:(A 24=\lambda 11, \bar{A} 24=\lambda 12, A 13=\lambda 4, \bar{A} 13=\lambda 5)$
flavor=3: all 15 bosons
The u-quarks have the composition ( $\mathrm{r}+, \mathrm{q}+$ ), and they are non-chiral, i.e. a superposition of ( $\mathrm{rL}+\mathrm{qR}+$ ) and (rR+,qL+). They are non-symmetric in $r$ and $q$, so their internal structure is cylinder-symmetric or ringsymmetric, therefore there are corrections to the standard gyromagnetic factor 2 , like for the nucleons. They carry the color charge, and do not appear separately, as the overall color must be zero (white).

The d-quarks have the composition ( $\mathrm{r}-\mathrm{q}+$ ), and they are non-chiral, i.e. a superposition of (rL-,qR+) and (rR-,qL+). They are non-symmetric in r and q , so their internal structure is cylinder-symmetric or ringsymmetric, therefore there are corrections to the standard gyromagnetic factor 2 , like for the nucleons. They carry the color charge, and do not appear separately, as the overall color must be zero (white).
D-quark flavors intermix via the CKM-matrix, its angles can be calculated (see dC-quark) by making a linear combination with variable CKM-angles, inserting into the hc-Lagrangian and minimizing. The solution is the energetically optimal CKM-mixture and yields the observed CKM-angles.

Energy distribution: preon(u1,u2) bosons Ai

4.6 Weak massive bosons $\mathbf{W m}, \mathrm{Z0}, \mathrm{ZL}, \mathrm{H}$

Spin $S=1$ or $=0$, one free particle u1: linear combination of two or four preons
Preon configuration:
$u=\left(0,0,\binom{u 1}{0}, 0\right)$ for weak exchange boson $\mathrm{Wm}\left(=\mathrm{W}^{--}\right)$
$u=\left(\binom{u 1}{0},\binom{0}{u 1},\binom{u 1}{0},\binom{0}{u 1}\right)$ for weak exchange boson Z0
$u=\left(\binom{u 1}{u 1},\binom{u 1}{u 1}, 0,0\right)$ for (hypothetical) left-chiral Z-boson ZL
$u=\left(\binom{u 1}{u 1},\binom{u 1}{u 1},\binom{u 1}{u 1},\binom{u 1}{u 1}\right)$ for higgs H
Boson configuration: only one flavor=3: all 15 bosons
The weak massive bosons are the Yukawa bosons of the hc-interaction, i.e. they mediate the residual force of the hc-interaction in the form of a exponentially decreasing potential. The L-projections of leptons and quarks interact via $\mathrm{SU}(2)$ and $(\mathrm{W}, \mathrm{Z})$ bosons, the R-projections of leptons and quarks interact via $\mathrm{SU}(1)$ and $\mathrm{Z0}$. This happens because of the $\mathrm{SU}(4)$-symmetry breaking $\mathrm{SU}(2)_{\mathrm{L}, \text { weak }} \otimes \mathrm{SU}(1)_{\mathrm{R}, \text { weak }} \otimes \mathrm{SU}(1)_{\mathrm{em}}$ with their exchange bosons $\left\{\mathrm{W}^{\mu}, \mathrm{Z}^{\mu}\right\} \otimes\left\{\mathrm{Z}^{\mu}\right\} \otimes\left\{\mathrm{A}^{\mu}\right\}$. The higgs H generates mass for leptons and quarks, and also for the r-preon. The sterile nc-neutrinos interact $\mathrm{SU}(2)$-weakly with neutrinos via ZL-boson.

4.7 Strong neutrinos (hypothetical) que qvm qvt

Spin $S=1 / 2$, two free preons, occupying fixed positions in the hc-tetra-spinor
Preon configuration: $u=\left(\binom{q L-}{0},\binom{0}{q L+}, 0,0\right)$
Boson configuration: flavor=1: $(A 12=\lambda 1)$, flavor=2: $(A 12=\lambda 1, \bar{A} 12=\lambda 2, A 34=\lambda 13, \bar{A} 34=\lambda 14)$ flavor=3: all 15 bosons

The strong neutrinos are neutral spherically symmetric particles with composition ( $\mathrm{q}+, \mathrm{q}^{-}$) and have masses starting with 23 MeV . They can hc-interact via Zq strong bosons, but only for high energies
$(\mathrm{E} \sim \mathrm{m}(\mathrm{Zq})=644 \mathrm{GeV})$, they are colorless and do not interact strongly. They are candidates for dark matter, as they are in the appropriate mass range (around 100 MeV , according to the new SIMP-scheme for dark matter), and they interact with themselves at high energies, as was observed for dark matter in certain galaxies.

### 4.8 Strong bosons (hypothetical) $\mathbf{Z q ~ H q}$

Spin $S=1$ or $=0$, one free particle u1: linear combination of two or four preons
Preon configuration:
$u=\left(\binom{u 1}{0},\binom{0}{u 1},\binom{u 1}{0},\binom{0}{u 1}\right)$ for strong exchange boson Zq
$u=\left(\binom{u 1}{u 1},\binom{u 1}{u 1},\binom{u 1}{u 1},\binom{u 1}{u 1}\right)$ for q-higgs Hq
Boson configuration; all hc-bosons active flavor=3
The strong boson Zq is the Yukawa-boson for the hc-interaction of q -netrinos. The strong higgs Hq generates masses for the q -neutrinos and for the q -preons.

## 5. Weak hadron decays in the $\mathrm{SU}(4)$-preon model

### 5.1 Neutron decay

The neutron decay obeys the scheme
$d d \rightarrow u d+e^{-}+\bar{v}_{e}$, i.e. for free neutrons $n \rightarrow p+e^{-}+\bar{v}_{e}$
with the mean lifetime of $\tau=881.5 \pm 1.5 \underline{\mathrm{~s}}$ and energy $\Delta \mathrm{E}=0.782343 \mathrm{MeV}$
In the SM it is described by the interaction of a virtual W -boson

$$
\mathrm{n}^{0} \rightarrow \mathrm{p}^{+}+\mathrm{w}^{-} \rightarrow \mathrm{p}^{+}+\mathrm{e}^{-}+\overline{\mathrm{v}}_{\mathrm{e}}
$$

With the probability of about $\mathrm{p}=0.001$, an additional photon is emitted

$$
n^{0} \rightarrow p^{+}+e^{-}+\bar{v}_{e}+y
$$

Currently, there is a "neutron lifetime puzzle": the lifetime measured by proton-counting (beam-method lifetime $\tau_{1}$ ) yields $\tau_{2}=\tau_{1}+8 \mathrm{~s}$, compared to the bottle-method (lifetime $\tau_{2}$ ) of counting the remaining neutrons. A possible explanation is the possibility of other decay channels for n .

In the SU4PM the decay proceeds as follows
$d(r R-, q L+) \rightarrow u(r L+, q R+)+W^{-}(r R-, r R-)+Z_{q}(q L-, q L+)$
$d(r L-, q R+) \rightarrow d(r R-, q L+)+Z_{L}(r L-, r L+)+\bar{Z}_{q}(q R-, q R+)$
with the immediate decay $W^{-}\left(r R-, r R^{-}\right) \rightarrow e^{-}\left(r L^{-}, r R^{-}\right)+\bar{v}_{e}(r R-, r R+)$
and the decay $Z_{L}(r L-, r L+) \rightarrow v_{e}(r L-, r L+)+v_{s 1}(r L+, r R-)$,
i.e the total reaction is
$n \rightarrow p+e^{-}+\bar{v}_{e}+v_{e}+v_{s 1}$, with the additional emission of a neutrino and a sterile neutrino, which are undetectable and carry away a small fraction of the total energy, ascribed to the antineutrino.
The neutrino and the antineutrino annihilate in a small fraction of events, producing an additional photon.
The virtual $Z_{q}$ and $\bar{Z}_{q}$ annihilate immediately and carry no energy away.

### 5.2 Transitions of quarks

A quark can make a transformation, which swaps the chirality of its components. This is seen at the example of a d-quark transition
$d(r L-, q R+) \rightarrow d(r R-, q L+)+Z_{L}(r L-, r L+)+\bar{Z}_{q}(q R-, q R+) \rightarrow d(r R-, q L+)+v_{e}(r L-, r L+)+\bar{v}_{q}(q R-, q R+)$
$d(r R-, q L+) \rightarrow d(r L-, q R+)+\bar{Z}_{L}(r R-, r R+)+Z_{q}(q L-, q L+) \rightarrow d(r L-, q R+)+\bar{v}_{e}(r R-, r R+)+v_{q}(q L-, q L+)$
Both transitions take at least the energy $\Delta \mathrm{E}=23 \mathrm{MeV}$ for the mass of $v_{q}$.
This transition can serve as an additional channel for the neutron decay:
$n \rightarrow n+\bar{v}_{e}+v_{e}+\bar{v}_{q}+v_{q}$, which takes away $\Delta \mathrm{E}=2 * 23 \mathrm{MeV}$ and makes fast neutrons slow, making them undetectable by the usual scintillation method. This would explain the "neutron lifetime puzzle".

### 5.3 Pion decay

The pion decay is the other major source of weak hadron decays, in the SM it is described as $u \bar{d} \rightarrow e^{+}+v_{e}$
In the SU4PM the decay proceeds as follows
$u(r R+, q L+) \rightarrow u(r L+, q R+)+\bar{Z}_{L}(r R-, r R+)+v_{q}(q L-, q L+)$
$\bar{d}(r L+, q R-) \rightarrow \bar{u}\left(r R-, q L^{-}\right)+W^{+}(r L+, r L+)+\bar{v}_{q}(q R-, q R+)$
the virtual W -boson and ZL -boson decay into electron and neutrinos
$W^{+}(r L+, r L+) \rightarrow e^{+}(r L+, r R+)+v_{e}(r L-, r L+)$
$\bar{Z}_{L}(r R-, r R+) \rightarrow \bar{v}_{e}(r R-, r R+)+v_{s 1}(r L-, r R+)$
so the overall reaction is
$u(r R+, q L+)+\bar{d}(r L+, q R-) \rightarrow u(r L+, q R+)+\bar{u}(r R-, q L-)+$
$+e^{+}(r L+, r R+)+v_{e}(r L-, r L+)+\bar{v}_{e}(r R-, r R+)+v_{s 1}(r L-, r R+), \mathrm{i}, \mathrm{e}$,
$u \bar{d} \rightarrow e^{+}+v_{e}+\bar{v}_{e}+v_{s 1}$, the pion decays into an electron and antineutrino plus the (undetectable) neutrino and sterile neutrino.
