Beta decay blackbody model

Vladimir Aksayskiy vladimir.aksayskiy@mail.ru

Abstract

The energy beta spectrum of radioactive beta emitters is similar to the continuous spectra of thermal radiation, thermionic emission and bremsstrahlung. A useful and universal way of describing such spectra is the blackbody model.

Introduction

Figure 1 shows a typical spectrum of a radioactive beta emitter. Beta decay is the main decay channel of 210Bi isotope, the contribution of alpha decay does not exceed 10^-4%. The half-life of 5 days.

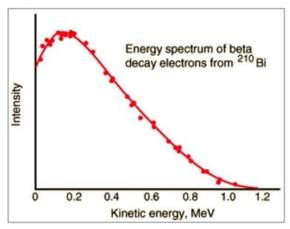

Fig. 1. Energy Spectrum of 210Bi Beta Decay Electrons from G.J. Neary.

Model

Let's say a beta emitter is a black body with a nuclear Fermi gas. Gas quasiparticles have a charge, not necessarily a whole, and obey Fermi-Dirac statistics. The presence of a charge allows the kinetic energy to be expressed in electrical units. The following is a fragment of a mathcad file with the simplest blackbody formula for 210Bi beta power density depending on the kinetic energy of the beta particles:

$$\begin{split} & \mathrm{fm} \coloneqq 10^{-15} \mathrm{m} & \mathrm{AMU} \coloneqq 1.66053886 \cdot 10^{-27} \cdot \mathrm{kg} \\ & \mathrm{h} \coloneqq 6.6260693 \cdot 10^{-34} \cdot \mathrm{J} \cdot \mathrm{s} & \mathrm{k_b} \equiv 1.3806505 \cdot 10^{-23} \cdot \frac{\mathrm{J}}{\mathrm{K}} \\ & \mathrm{eV} \equiv 1.602176565 \cdot 10^{-19} \mathrm{J} & \mathrm{MeV} \equiv 10^6 \mathrm{eV} \\ \hline \\ & \overline{\mathrm{m}_{\mathrm{Bi}} \coloneqq 210\mathrm{AMU}} & \mathrm{r_{\mathrm{Bi}} \coloneqq 1.23 \mathrm{fm} \cdot \sqrt[3]{210}} & \mathrm{r_{\mathrm{Bi}} = 7.311 \, \mathrm{fm}} \\ & \mathrm{n_{fg} \coloneqq \frac{1}{\mathrm{r_{\mathrm{Bi}}}^3}} & \mathrm{n_{fg}} = 2.559 \times 10^{42} \frac{1}{\mathrm{m}^3} & \mathrm{fermi-gas\ concentration\ in\ 210\mathrm{Bi}} \\ & \mathrm{E_{peak} \coloneqq 0.23\mathrm{MeV}} & \mathrm{T_{\mathrm{K}} \coloneqq 0.80 \cdot 10^9 \cdot \mathrm{K}} \\ & \mathrm{PD}\big(\mathrm{E},\mathrm{T_{\mathrm{K}}}\big) \coloneqq \frac{\mathrm{E}^2 \cdot \mathrm{n_{fg}}}{\mathrm{h}} \cdot \frac{1}{\frac{2 \cdot \mathrm{E}}{\mathrm{s}^3 \cdot \mathrm{k_b} \cdot \mathrm{T_{\mathrm{K}}}} & \mathrm{black\ body\ formula} \\ & \mathrm{for\ beta\ spectrum\ 210\mathrm{Bi}} \\ & \mathrm{PD}\big(\mathrm{E_{peak}},\mathrm{T_{\mathrm{K}}}\big) = 5.118 \times 10^{47} \frac{\mathrm{W}}{\mathrm{m}^3} & \mathrm{PDa}\big(\mathrm{E},\mathrm{T_{\mathrm{K}}}\big) \coloneqq \frac{\mathrm{PD}\big(\mathrm{E},\mathrm{T_{\mathrm{K}}}\big)}{\mathrm{PD}\big(\mathrm{E_{peak}},\mathrm{T_{\mathrm{K}}}\big)} \end{split}$$

Figure 2 allows you to visually compare the beta spectrum of 210Bi according to the blackbody formula with the experimental spectrum from the article by G.J. Neary.

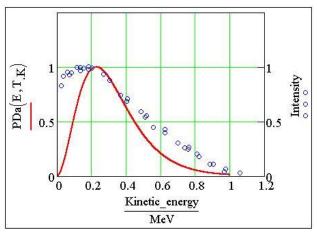

Fig. 2. The energy spectrum of 210Bi beta decay electrons according to the blackbody formula (red line) and the experimental spectrum from G.J. Neary's article (blue dots).

Conclusions

It seems that it is possible to search neutrino of beta decay in details of the shape of experimental spectrum that distinguish it from blackbody model.

A curious prediction of the model is the very high temperature of the nuclear Fermi gas. If this is true, then experimentally detecting the dependence of beta decay on temperature will not be a very simple task.
