# Planck's spectrum as function of wavelength is untenable 

Sjaak Uitterdijk<br>SjaakenLutske@hetnet.nl

Abstract-Scrutinizing Planck's spectra as function of frequency and as function of wavelength learns that the last mentioned one leads to baffling results.

## 1 Introduction

Planck's book about this subject, originally written in 1913, has been translated to English as shown in [1]. He presents two types of spectra for the so-called black body radiation, one as function of frequency, the other one as function of wavelength. The second one turns out to be untenable.

## 2 The black body radiation spectrum as function of frequency and wavelength

Planck presented the following two spectra, supplemented with his commentary in Italics:

$$
\mathrm{K}_{v}=h v^{3} c^{-2} /(\exp (h v / \mathrm{kT})-1) \quad \mathrm{W} / \mathrm{m}^{2} / \mathrm{Hz}
$$

"This is the specific intensity of a monochromatic plane polarized ray of the frequency $v$ which is emitted from a black body at the temperature T into vacuum in a direction perpendicular to the surface."

$$
\mathrm{E}_{\lambda}=\left(h c^{2} \lambda^{-5}\right) /(\exp (b c / \mathrm{k} \lambda \mathrm{~T})-1) \quad \mathrm{W} / \mathrm{m}^{2} / \mathrm{m}
$$

"This is the specific intensity of a monochromatic ray not to the frequency $v$ but, as is usually done in experimental physics, to the wavelength $\lambda . .$. "

The spectrum $\mathrm{E}_{\lambda}$ is incorrect for the following 3 reasons:
1 the maximum of $E_{\lambda}$ is not at the same frequency as of $K_{v}$
$2 \quad K_{v}$ and $E_{\lambda}$ show an incomprehensible relationship
3 the dimension of $E_{\lambda}$ is meaningless/unphysical
ad 1 The maximum of $K_{v}$ is found for $d K_{v} / d v=3 v^{2} \cdot\left(e^{a v}-1\right)^{-1}-v^{3} \cdot\left(e^{a v}-1\right)^{-2} \cdot e^{a v} \cdot a=3-a v /\left(1-e^{-a v}\right)=0$

Approximating $1-e^{-a v} \quad$ by $\quad \mathrm{av}-\mathrm{a}^{2} v^{2} / 2 \quad$ leads to $v=(4 / 3) \cdot a^{-1}=(4 / 3) \mathrm{kT} / \mathrm{h} \quad \mathrm{Hz}$
Approximating $1-e^{-a v} \quad$ by $\quad a v-a^{2} v^{2} / 2+a^{3} v^{3} / 6 \quad$ leads to $v=4 \cdot a^{-1}=4 \mathrm{kT} / b \quad \mathrm{~Hz}$
Approximating $\left(\mathrm{e}^{\text {av }}-1\right)^{-1} \quad$ by $\quad \mathrm{e}^{-\mathrm{av}}$ directly in $\mathrm{K}_{v} \quad$ leads to $v=3 \cdot a^{-1}=3 \mathrm{kT} / h \quad \mathrm{~Hz}$

The numerical calculation of $K_{v}$ shows that the latter approximation is accurately close to reality.
This approximation applied to $\mathrm{E}_{\lambda}$ and replacing $1 / \lambda$ by y, leads to $\mathrm{E}_{\mathrm{y}}=h c^{2} \mathrm{y}^{5} \cdot \mathrm{e}^{-\mathrm{by}}$, with $\mathrm{b}=h c / \mathrm{kT}$.
$\mathrm{dE}_{\mathrm{y}} / \mathrm{dy}=5 \mathrm{y}^{4} \cdot e^{-\mathrm{by}}+\mathrm{y}^{5} \cdot(-\mathrm{b}) \cdot \mathrm{e}^{-\mathrm{by}}=5-\mathrm{y} \cdot \mathrm{b}=0$, so the maximum of $\mathrm{E}_{\lambda}$ is found at $v=5 \mathrm{kT} / h$.
ad 2 The cause of the deviation from $v=3 \mathrm{kT} / h$ in $\mathrm{K}_{v}$ is only the power 5 of $1 / \lambda$ in $\mathrm{E}_{\lambda}$.
Writing blindly $h c^{2} / \lambda^{3}$ instead of $h c^{2} / \lambda^{5}$ would lead to the dimension W $/ \mathrm{m}$ instead of $\mathrm{W} / \mathrm{m}^{2} / \mathrm{m}$ of $\mathrm{E}_{\lambda}$.
The solution to this problem should be found in the introduction of a constant with dimension $\mathrm{m}^{-2}$, instead of the introduction, as Planck did, of $\lambda^{-2}$. However such a constant does not exist. In order to show the mutual incomprehensible relationship between $K_{v}$ and $E_{\lambda}$ their maximum values are compared.
Applying $v=3 \mathrm{kT} / h$ in $K_{v}$ results in $K_{v m a x}=9.5 \cdot 10^{-20} \cdot \mathrm{~T}^{3} \quad \mathrm{~W} / \mathrm{m}^{2} / \mathrm{Hz}$
Applying $v=5 \mathrm{kT} / h$ in $\mathrm{E}_{\lambda}$ results in $\mathrm{E}_{\lambda \text { max }}=2.0 \cdot 10^{-6} \cdot \mathrm{~T}^{5}$
$\mathrm{W} / \mathrm{m}^{2} / \mathrm{m}$
These results show the already mentioned weird relationship, as well as the fact that $E_{\lambda}$ has to be rejected.
Ad3 The correct expression for $E_{\lambda}$ is found when $v^{3}$ in $K_{v}$ is replaced by $c^{3} / \lambda^{3}$ and $E_{\lambda}$ is written as $E_{v}$ :

$$
\mathrm{E}_{\mathbf{v}}=\left(b c / \lambda^{3}\right) /(\exp (h c / \mathrm{k} \lambda T)-1) \quad \mathrm{W} / \mathrm{m}^{2} / \mathrm{Hz}
$$

The index $v$ is chosen to emphasize that the integration of this spectrum has to be done w.r.t. the frequency. In a numerical situation, where $\lambda$ is taken as the primary variable, $\Delta \lambda$ (being $\lambda_{n}-\lambda_{n-1}$ ) has to be replaced by $\Delta \nu$ as $\left.c / \lambda_{n-1}-c / \lambda_{n}\right)$.

## 3 The most likely cause of the incorrect spectrum $\mathbf{E}_{\boldsymbol{\lambda}}$

This cause can be found by using the simplified shape, in order to show what happens with the integration of the spectrum as proposed by Planck. Replacing $\lambda^{-1}$ by y results in the following equations:

$$
\begin{gathered}
\int \mathrm{E}_{\lambda} \mathrm{d} \lambda=h c^{2} \int \lambda^{-5} \mathrm{e}^{-b c / \mathrm{k} \lambda \mathrm{~T}} \mathrm{~d} \lambda \quad \text { becomes } \int \mathrm{E}_{\mathrm{y}} \mathrm{dy}=h c^{2} \int \mathrm{f}(\mathrm{y}) \cdot \mathrm{y}^{5} \mathrm{e}^{-\mathrm{by}} \mathrm{~d}\left(\mathrm{y}^{-1}\right) \quad \text { with } \mathrm{b}=h c / \mathrm{kT} \\
\mathrm{dy}{ }^{-1} / \mathrm{dy}=-\mathrm{y}^{-2}, \text { so dy }{ }^{-1}=-\mathrm{y}^{-2} \text { dy, so } \mathrm{f}(\mathrm{y})=-\mathrm{y}^{-2} \text {, resulting in: } \int \mathrm{E}_{\mathrm{y}} \mathrm{dy}=-h c^{2} \int \mathrm{y}^{3} \mathrm{e}^{-\mathrm{by}} \mathrm{dy}
\end{gathered}
$$

Three times in a row integrating by parts delivers $\int_{0}{ }^{2} \mathrm{E}_{\mathrm{y}} \mathrm{dy}=b c^{2} \cdot 6 \cdot b^{-4}=6 \cdot h^{-3} c^{-2} \mathrm{k}^{4} \cdot \mathrm{~T}^{4}$, being equal to the integration of the simplified spectrum of $K_{v}$, implicitly as function of the frequency.

That implies that, notwithstanding the fact that $\mathrm{E}_{\lambda}$ as power density spectrum is fundamentally wrong, its power density is correct, when integrated w.r.t. the wavelength.

As shown in section 1 the maximum value of $E_{\lambda}$ as well its position, expressed in either frequency or wavelength, is wrong. For example at $\mathrm{T}=5777 \mathrm{~K}$ in the simplified spectra:
$\mathrm{E}_{\lambda \text { max }}=2.0 \cdot 10^{-6} \cdot \mathrm{~T}^{5}=1.3 \cdot 10^{4} \mathrm{~W} / \mathrm{m}^{2} / \mathrm{nm}$, at $\lambda \sim c /(5 \mathrm{kT} / h) \sim 500 \mathrm{~nm}$, at $v \sim 5 \mathrm{kT} / b \sim 600 \mathrm{THz}$
$\mathrm{K}_{\mathrm{vmax}}=9.5 \cdot 10^{-20} \cdot \mathrm{~T}^{3}=1.8 \cdot 10^{-8} \mathrm{~W} / \mathrm{m}^{2} / \mathrm{Hz}$, at $\lambda \sim c /(3 \mathrm{kT} / h) \sim 900 \mathrm{~nm}$, at $v \sim 3 \mathrm{kT} / h \sim 360 \mathrm{THz}$

The ratio $1.8 \cdot 10^{-8} \mathrm{Wm}^{-2} \mathrm{~Hz}^{-1} / 1.3 \cdot 10^{4} \mathrm{Wm}^{-2} \mathrm{~nm}^{-1}=1.4 \cdot 10^{-12} \mathrm{~nm} / \mathrm{Hz}$ doesn't show a meaningful outcome, due to the dimension $\mathrm{m} / \mathrm{Hz}$, and (as a result) as well as due to the numerical outcome. But still the curves are used, as shown below.

Mind the presented maximum value in the upper graph: 1.8 , instead of $1.3 \cdot 10^{4} \mathrm{~W} / \mathrm{m}^{2} / \mathrm{nm}$ ! Is it coincidental that the number 1.8 shows up too in $K_{v m a x}$ as $1.8 \cdot 10^{-8} \mathrm{Wm}^{-2} / \mathrm{Hz}$ ? See reference [2] for the interpretation of the extraterrestrial solar spectral radiation.

The surprising accuracy of the position of the maximum value in the simplified spectrum has been the motivation to draw the graphs of $\mathrm{K}_{v}$ and $\mathrm{E}_{\mathrm{v}}$ for both Planck's original and the simplified spectra.

Graph of $K_{v}$

Graph of $E_{\boldsymbol{v}}$

## Conclusion

The originally by Planck proposed spectrum as function of wavelength has to be rejected and replaced by his spectrum as function of frequency in which the variable $v$ simply is replaced by $c / \lambda$.
