

Evaluating the Alignment of the Polarized Radio Waves from 27 QSOs in a Region near the NGP

*Richard Shurtleff**

Abstract

The sample of 27 quasars with polarized radio emissions located in a region near the North Galactic Pole is shown to have highly aligned polarization directions. Furthermore, by extending their polarization directions around the Celestial Sphere, the convergence of their polarization directions is shown to be close to the sources. Thus, parallax forces the position angles to vary with locations of individual sources. One suspects that, whatever physical explanation fits, the explanation for converging close to the sample is different from the explanation for alignments with near-equal position angles that converge far from the sample on the sky. The alignment is analyzed in this Mathematica notebook. Access to a .nb notebook is provided in the references.

Keywords: Polarized Radio Sources; Alignment; Quasi-stellar objects

0. Preface

The pdf version of this notebook is available online from the viXra archive.
To find the ready-to-run notebook follow the link in Ref. 1.

Notes:

- (1) The pdf version quotes some numerical values that are associated with the particular settings and uncertainty runs that were current when the pdf version was created. Other sets of uncertainty runs, for a sufficiently large number of runs, should alter those numerical values only slightly.
- (2) The notebooks in this series were created using Wolfram Mathematica, Version Number: 12.1, Ref. 2.
- (3) The formulas for creating Aitoff plots were found on Wikipedia, Ref. 3.

The Hub Test

This notebook presents an application of the Hub Test, which is discussed more fully in Ref. 4. The basic idea is that polarization directions are well-aligned with each other when they are well-aligned with some point on the Celestial Sphere.

Consider the well-known prescription for finding Polaris, the North Star, based on the alignment of the direction from the Merak to Dubhe with Polaris. Guided by Fig. 1, let the source S be the star Merak, take the interval from Merak to Dubhe in place of the direction of polarization \hat{v}_ψ , and let Polaris be the point H . Then the alignment of the Merak to Dubhe direction \hat{v}_ψ with Polaris, the

point H , illustrates the concept of alignment in the Hub Test. With Merak as S , Merak-Dubhe as \hat{v}_ψ , and Polaris as H , the angle η would be about $\eta = 3.47^\circ$. In that case, the blue great circle and the purple great circle in Fig. 1 would almost coincide.

Figure 1: The Celestial sphere is pictured on the left and on the right is the plane tangent to the sphere at the source S . The linear polarization direction \hat{v}_ψ lies in the tangent plane and determines the purple great circle on the sphere. A point H on the sphere and the point S determine a second great circle, the blue circle drawn on the sphere at the left. Clearly, H and S must be distinct in order to determine a great circle.

In Fig. 1, the “alignment angle” η is the acute angle η between the great circles at S , $0^\circ \leq \eta \leq 90^\circ$. The alignment angle η measures how well the polarization direction \hat{v}_ψ matches the direction toward the point H . Perfect alignment occurs when $\eta = 0^\circ$ and the two great circles overlap. Perpendicular great circles, $\eta = 90^\circ$, indicates maximum “avoidance” of the polarization direction \hat{v}_ψ with the point H on the sphere. The halfway value, $\eta = 45^\circ$, favors neither alignment nor avoidance.

With N sources S_i , $i = 1, \dots, N$, there are N alignment angles η_{iH} for the point H and an average alignment angle $\bar{\eta}$ at H ,

$$\bar{\eta}(H) = \frac{1}{N} \sum_{i=1}^N \eta_{iH} . \tag{1}$$

The alignment angle $\bar{\eta}(H)$ is a function of position H on the sphere. It is symmetric across diameters, $\bar{\eta}(H) = \bar{\eta}(-H)$, because great circles are symmetric across diameters.

The function $\bar{\eta}(H)$ measures convergence and divergence of the great circles determined by the polarization directions. For random polarization directions, the average $\bar{\eta}(H)$ should be near 45° , since each alignment angle η_{iH} is acute, $0^\circ \leq \eta_{iH} \leq 90^\circ$, and random polarization directions should not favor any one value. Points H where the alignment angle $\bar{\eta}(H)$ is smaller than 45° , the great circles tend to converge, where $\bar{\eta}(H)$ is larger than 45° , the great circles can be said to diverge.

Thus the basic concept includes “avoidance”, as well as alignment. Avoidance is high when the two directions \hat{v}_ψ and \hat{v}_H differ by a large angle, $\eta \rightarrow 90^\circ$. Perpendicular great circles at S , $\eta = 90^\circ$, would indicate the maximum avoidance of the polarization direction and the point on the sphere. The N sources’ polarization directions most avoid the points H_{\max} and $-H_{\max}$ where the function $\bar{\eta}(H)$ takes its maximum value $\bar{\eta}_{\max}$. The locations of the most extreme divergence are called “avoidance hubs”.

The N sources’ polarization directions are best aligned with the points H_{\min} and $-H_{\min}$ where the alignment angle is a minimum $\bar{\eta}_{\min}$. The locations H_{\min} and $-H_{\min}$ of their most extreme convergence are called “alignment hubs”. Alignment and avoidance are equally viable, complementary concepts with the Hub Test.

The Hub test provides many calculated results to describe the collective behavior of the polarization directions in a sample. The alignment angle function $\bar{\eta}(H)$, Eq. (1), can be mapped on the Celestial Sphere to give a visual display. The smallest alignment angle $\bar{\eta}_{\min}$ and the largest avoidance angle $\bar{\eta}_{\max}$ quantify the agreement of the directions. Known formulas, see Sec. 4 below, are available to calculate the significance of the alignment, *i.e.* the likelihood that random polarization directions would yield better results. The locations of the convergence hubs H_{\min} and the divergence hubs H_{\max} may provide clues to magnetic field direction and such quantities.

1. Introduction

Electromagnetic radiation from QSOs has traveled a long way and, no doubt, has been passed along by various intergalactic media. Alternatively, it may be that the radio waves are polarized when emitted at the source. Either way, to have regions of the sky containing QSOs with aligned polarization, or some other way correlated, is certainly remarkable. It has been suggested, Ref. 5, that the polarization levels are too strong, a percent to several percent, for the cause to be local to the Milky Way. With the Coma Supercluster in the same general direction as these QSOs, some mechanism may be able to explain the alignment as occurring

enroute, or, as mentioned before, the polarizations could exist when the radio waves are emitted and then some other mechanism would be needed. In any case, the alignment is remarkable.

In this notebook, we analyze the alignment tendencies of the sample of 27 radio QSOs. The sample occupies a roughly 11° radius patch of sky centered on $(RA,dec) = (178^\circ, 10^\circ)$ and is chosen based on a whole-sky survey of the radio QSOs in the Pelgrims 2014 catalog, Ref. 6. The survey populated 5° -radius regions centered on the grid points of a 2° mesh and calculated the significance of each region's polarization direction alignment. See Fig. 3. The group that contains the 27 QSOs that are analyzed in this notebook consists of 14 very significantly aligned 5° -radius regions near the North Galactic Pole, one of which happens to be the most significantly aligned of all of the 5° regions.

The 27 QSOs in the sample make 27 great circles along the polarization directions. The smallest alignment angle $\bar{\eta}(H)$ occurs for at a hub H_{\min} less than 15° southeast from the center of the sample. When the hub is this close, the polarization directions from different places in the sample must have different position angles due to parallax. The hub test has the advantage that it can detect such correlations.

2. Coordinates, grid, and sundry basic formulas

2a. Coordinates

Consider the “Celestial Sphere”, a sphere in 3 dimensional Euclidean space. See Fig. 1 in the Preface. The sphere is also called the “sphere” or sometimes “the sky”. The center of the sphere is the origin of a 3D Cartesian coordinate system with coordinates (x, y, z) . The direction of the positive z -axis is due “North”. Equatorial longitude is the Right Ascension α and latitude is the declination δ .

From a point-of-view located outside the sphere, as in the sketch in Fig. 1, one pictures a source S plotted on the sphere and, in the 2D tangent plane at S , local North is upward and local East is to the right. A “position angle” at the point S on the sphere, such as the angle ψ in Fig. 1, is measured in the 2D plane tangent to the sphere at S . In the tangent plane as drawn in Fig.1, the position angle ψ is measured clockwise from local North with East to the right.

Definitions:

e_r, e_N, e_E are unit vectors in a 3D Cartesian coordinate system

(α, δ) = equatorial coordinates longitude and latitude

$e_r(\alpha, \delta)$ = radial unit vectors from Origin

$e_N(\alpha, \delta)$ = local North at a point on the Celestial Sphere

$e_E(\alpha, \delta)$ = local East at a point on the Celestial Sphere

$\alpha_{FROMr}(e_r)$ = α determined by radial unit vector e_r

$\delta_{FROMr}(e_r)$ = δ determined by radial unit vector e_r

Aitoff Plot Functions

$\alpha_H(\alpha, \delta)$, $x_H(\alpha, \delta)$, $y_H(\alpha, \delta)$, where x_H is centered on $\alpha = 0$ and α increases from left-to-right, with $\alpha = -180^\circ$ on the left and $+180^\circ$ on the right

$x_{H180}(\alpha, \delta)$, $y_{H180}(\alpha, \delta)$, where x_H is centered on $\alpha = 180^\circ$ and α increases from left-to-right, with $\alpha = 0^\circ$ on the left and 360° on the right

```

 {0} = Union[Flatten[Simplify[{er[ $\alpha$ ,  $\delta$ ].er[ $\alpha$ ,  $\delta$ ] - 1, er[ $\alpha$ ,  $\delta$ ].eN[ $\alpha$ ,  $\delta$ ], er[ $\alpha$ ,  $\delta$ ].eE[ $\alpha$ ,  $\delta$ ],
 eN[ $\alpha$ ,  $\delta$ ].eN[ $\alpha$ ,  $\delta$ ] - 1, eN[ $\alpha$ ,  $\delta$ ].eE[ $\alpha$ ,  $\delta$ ], eE[ $\alpha$ ,  $\delta$ ].eE[ $\alpha$ ,  $\delta$ ] - 1, Cross[er[ $\alpha$ ,  $\delta$ ], eE[ $\alpha$ ,  $\delta$ ] -
 eN[ $\alpha$ ,  $\delta$ ], Cross[eE[ $\alpha$ ,  $\delta$ ], eN[ $\alpha$ ,  $\delta$ ] - er[ $\alpha$ ,  $\delta$ ], Cross[eN[ $\alpha$ ,  $\delta$ ], er[ $\alpha$ ,  $\delta$ ] - eE[ $\alpha$ ,  $\delta$ ]}]]]}

Out[ ]:= {Check er.er = 1, er.eN = 0, er.eE = 0, eN.eN = 1,
 eN.eE = 0, eE.eE = 1, erXeE = eN, eEXeN = er, eNXer = eE: , True}

```

Get (α, δ) in radians from a radial vector r:

```

In[ ]:=  $\alpha$ FROMr[r_] := N[ArcTan[Abs[r[[2]]/r[[1]]]] /; (r[[2]] >= 0 && r[[1]] > 0)
 $\alpha$ FROMr[r_] := N[ $\pi$  - ArcTan[Abs[r[[2]]/r[[1]]]] /; (r[[2]] >= 0 && r[[1]] < 0)
 $\alpha$ FROMr[r_] := N[ $\pi$  + ArcTan[Abs[r[[2]]/r[[1]]]] /; (r[[2]] < 0 && r[[1]] < 0)
 $\alpha$ FROMr[r_] := N[2.  $\pi$  - ArcTan[Abs[r[[2]]/r[[1]]]] /; (r[[2]] < 0 && r[[1]] > 0)
 $\alpha$ FROMr[r_] :=  $\pi$ /2. /; (r[[2]] >= 0 && r[[1]] == 0)
 $\alpha$ FROMr[r_] := 3  $\pi$ /2. /; (r[[2]] < 0 && r[[1]] == 0)

 $\delta$ FROMr[r_] := N[ArcTan[r[[3]] / ( $\sqrt{r[[1]]^2 + r[[2]]^2}$ )] /; ( $\sqrt{r[[1]]^2 + r[[2]]^2}$  > 0)
 $\delta$ FROMr[r_] := Sign[r[[3]]] ( $\pi$ /2.) /; ( $\sqrt{r[[1]]^2 + r[[2]]^2}$  == 0)

```

The following Aitoff Plot formulas can be found in Wikipedia, Ref. 3.

For these formulas the angles α and δ should be in degrees.

They give an Aitoff Plot that is centered on $(0^\circ, 0^\circ)$

```

In[ ]:=  $\alpha$ H[ $\alpha$ _,  $\delta$ _] :=  $\alpha$ H[ $\alpha$ ,  $\delta$ ] = ArcCos[Cos[ ((2.  $\pi$ ) / 360.)  $\delta$ ] Cos[ ((2.  $\pi$ ) / 360.)  $\alpha$  / 2. ] ]
xH[ $\alpha$ _,  $\delta$ _] := xH[ $\alpha$ ,  $\delta$ ] = (2. Cos[ ((2.  $\pi$ ) / 360.)  $\delta$ ] Sin[ ((2.  $\pi$ ) / 360.)  $\alpha$  / 2. ] ) / Sinc[ $\alpha$ H[ $\alpha$ ,  $\delta$ ]]
yH[ $\alpha$ _,  $\delta$ _] := yH[ $\alpha$ ,  $\delta$ ] = Sin[ ((2.  $\pi$ ) / 360.)  $\delta$ ] / Sinc[ $\alpha$ H[ $\alpha$ ,  $\delta$ ]]

```

Using the following functions produces an Aitoff Plot that is centered on $(180^\circ, 0^\circ)$

```

In[ ]:=
xH180[ $\alpha$ _,  $\delta$ _] :=
  xH180[ $\alpha$ ,  $\delta$ ] = (2. Cos[ ((2.  $\pi$ ) / 360.)  $\delta$ ] Sin[ ((2.  $\pi$ ) / 360.) ( $\alpha$  - 180.) / 2. ] ) / Sinc[ $\alpha$ H[ ( $\alpha$  - 180.),  $\delta$ ]]
yH180[ $\alpha$ _,  $\delta$ _] := yH180[ $\alpha$ ,  $\delta$ ] = Sin[ ((2.  $\pi$ ) / 360.)  $\delta$ ] / Sinc[ $\alpha$ H[ ( $\alpha$  - 180.),  $\delta$ ]]

```

2b. Grid, sometimes called a mesh

We avoid bunching at the poles by taking into account the diminishing radii of constant latitude circles as the latitude approaches the poles. Successive grid points along any latitude or along any longitude make an arc that subtends the same central angle $d\theta$.

We grid one hemisphere at a time, then the grids are combined.

Definitions:

gridSpacing separation in degrees between grid points on and between constant latitude circles

d θ 1	grid spacing in radians
idN, ai, ji	dummy indices, ID #s for grid points, longitude, latitude
α pointH, δ pointH	α and δ of the grid points H_j
grid, gridN, gridS	tables data associated with grid points, listings are below
nGrid	number of grid points
α Grid	longitudes at the grid points ($-\pi \leq \alpha \leq +\pi$)
δ Grid	latitudes at the grid points ($-\pi/2 \leq \alpha \leq \pi/2$)
rGrid	radial unit vectors from origin to grid points, in 3D Cartesian coordinates

2c. The mean and standard deviation are convenient functions. And we identify directories for getting and putting data.

Definitions

mean the arithmetic average of a set of numbers, $\frac{1}{N} \sum_{i=1}^N n_i$

stanDev the standard deviation. Given a set of N numbers n_i with mean value m , the standard deviation is $\left(\frac{1}{N} \sum_{i=1}^N (n_i - m)^2\right)^{1/2}$, the square root of the average of the squares of the differences of the numbers with the mean. Note that we divide by N to get the average of the deviations squared.

catalogDirectory directory containing the catalog files

The grid points are separated by gridSpacing = 2.° arcs along latitude and longitude.

The number of grid points is 10518 .

3. Polarization and Position Data

3a. Data

The Pelgrims 2014 catalog incorporates data from the large JVAS/CLASS 8.4 Ghz catalog Jackson 2007, Refs. 6 and 7. The Pelgrims 2014 catalog sources were filtered from Jackson 2007 sources by identification as QSOs, for percent polarization, $p > 0.6\%$,

for the largest fractional uncertainty in percent polarization, $\sigma_p/p < 0.6\%$, and for uncertainty in the polarization position angle $\sigma_\psi < 16^\circ$. The data is converted to convenient units, angles in radians, and reordered in a notebook. The result is the basic data file “data00”.

(The files on my computer: 20200713JVAS1450Todata00a.nb, 20200718data08JVAS1450.dat, JVAS_1450A.dat.txt, 20210418Survey1450QSOs.nb .)

Definitions:

3a. Section Summary

We consider Quasi-Stellar Objects, QSOs. The data is found in Pelgrims 2014, Ref. 6, a catalog of 1450 QSOs that have been identified as QSOs in the earlier JVAS/CLASS 8.4Ghz catalog Jackson 2007 that has 12700 records. Ref. 7 Then 5° radius regions are constructed, one on each of the 10518 grid points as in Sec. 2b. The 1450 QSOs were assigned to the regions based on location and we calculated the significance of the alignment of the polarization directions for the sources in each region.

The QSOs selected for this notebook satisfied many requirements: (i) have 7 or more sources in order to use the significance formulas in Sec. 4 accurately, (ii) have longitude RA $165^\circ \leq \alpha \leq 200^\circ$, (iii) have latitude dec $0^\circ \leq \delta \leq 30^\circ$, (iv) whose QSOs are very significantly aligned, $S \leq 10^{-2}$. There are 14 regions satisfying (i) - (iv) containing a total of 27 sources.

Figure 3. Survey of polarized radio QSOs. (Equatorial Coordinates, centered at $(\alpha, \delta) = (180^\circ, 0^\circ)$, $\alpha = 360^\circ$ on the right.) The 1450 QSOs were grouped into 5° radius regions centered on grid points. Those regions having at least 7 QSOs are plotted as gray dots at the central grid point. Just 35 regions showed very significant alignment, *i.e.* $S \leq 0.01 = 10^{-2}$, or, equivalently, $-\text{Log}_{10} S \geq 2.0$, and these are plotted as color dots. The indicated clump of 14 regions was selected for the analysis. There are 27 QSOs in the combined area of the 14 regions.

Sample Size: The angular separation of the furthest QSO from the sample center is 11.1277° .

4a. Formulas

The problem of “significance” is to determine the likelihood that random polarizations directions would have better alignment or avoidance than the observed polarization directions. To determine the probability distributions and related formulas, in a previous notebook, we made many runs with random data and fit the results.

For samples with randomly directed polarization vectors, the basic formula, Eq. 1, looks like the sum of random numbers each restricted to the range 0 to π . Such random sums can be related to well-known Random Walk scenarios. That connection helps explain the dependence on \sqrt{N} in the formulas below.

Definitions:

norm	a constant used to normalize the distribution so the integral of probability is 1.
probMIN0, probMAX0	probability distributions for alignment (MIN) and avoidance (MAX), functions of η, η_0, σ
$\rho_{ci}ai_{MIN,MAX}$	constants used in the formulas to mean η_0 and uncertainty σ
$\sigma_{\rho_{ci}ai_{MIN,MAX}}$	uncertainty σ in the constants used in the formulas to mean η_0 and uncertainty σ
regionRadiusChoices	radii used in random runs performed elsewhere, not in this notebook
regionChoice	determines the best choice for the current sample
rgnRadius	assumed radius of the region for the purpose of selecting the statistics constants c_i and a_i
$i\rho$	dummy variable used to select region radius
$ci_{MIN,MAX}$ and $ai_{MIN,MAX}$	parameters for statistics formulas for η_0 and σ
$\eta_{0MIN, MAX}$	function to estimate mean η_0
$\sigma_{MIN, MAX}$	function to estimate uncertainty σ
probMIN, probMAX	probability distributions using estimated values of η_0, σ
signiMIN0, signiMAX0	significance as a function of (η, η_0, σ)
signiMIN, signiMAX	significance of η using estimated values of η_0, σ

$$ln[*]:= (* y = ((\eta - \eta_0)/\sigma); dy = d\eta/\sigma *)$$

(* The normalization factor "norm" is needed for the probability density *)

$$\text{norm} = \left(\frac{1}{(2\pi)^{1/2}} \text{NIntegrate} \left[(1 + e^{4(y-1)})^{-1} e^{-\frac{y^2}{2}}, \{y, -\infty, \infty\} \right] \right)^{-1};$$

norm; (*Constant needed to make the integral of the probability distribution equal to unity.*)

$$ln[*]:= \text{probMIN0}[\eta_-, \eta_0_-, \sigma_-] := \left(\frac{\text{norm}}{\sigma (2\pi)^{1/2}} \right) \left(1 + e^{4 \frac{(\eta - \eta_0 - \sigma)}{\sigma}} \right)^{-1} e^{-\frac{1}{2} \left(\frac{\eta - \eta_0}{\sigma} \right)^2}$$

$$\text{signiMIN0}[\eta_-, \eta_0_-, \sigma_-] := \text{NIntegrate}[\text{probMIN0}[\eta_1, \eta_0, \sigma], \{\eta_1, -\infty, \eta\}]$$

$$ln[*]:= \text{probMAX0}[\eta_-, \eta_0_-, \sigma_-] := \left(\frac{\text{norm}}{\sigma (2\pi)^{1/2}} \right) \left(1 + e^{-4 \frac{(\eta - \eta_0 + \sigma)}{\sigma}} \right)^{-1} e^{-\frac{1}{2} \left(\frac{\eta - \eta_0}{\sigma} \right)^2}$$

$$\text{signiMAX0}[\eta_-, \eta_0_-, \sigma_-] := \text{NIntegrate}[\text{probMAX0}[\eta_1, \eta_0, \sigma], \{\eta_1, \eta, \infty\}]$$

The significance $\text{signiMIN0}[\eta, \eta_0, \sigma]$ is the Integral of probMIN0 , i.e. $\text{signiMIN0} = \int_{-\infty}^{\eta} P_{\text{MIN}}(\eta) d\eta$.

The significance $\text{signiMAX0}[\eta, \eta_0, \sigma]$ is the Integral of probMAX0 , i.e. $\text{signiMAX0} = \int_{\eta}^{\infty} P_{\text{MAX}}(\eta) d\eta$.

The formulas for mean $\eta_0 = \frac{\pi}{4} \pm \frac{c_1}{N^{a_1}}$ and half-width $\sigma = \frac{c_2}{4N^{a_2}}$ estimate η_0 and σ by functions of the number N of sources.

These formulas depend on the size of the region (radius ρ) by the choice of parameters c_i and a_i , $i = 1, 2$. The following values for the parameters c_i and a_i are based on random runs. For each combination of $N = \{8, 16, 32, 64, 128, 181, 256, 512\}$ and $\rho = \{0^\circ, 5^\circ, 12^\circ, 24^\circ, 48^\circ, 90^\circ\}$, there were 2000 random runs completed.

A notation conflict between this notebook and the article, Ref. 4, should be noted. We doubled the exponent “a” so $N^{a/2}$ appears in the article, whereas in the formulas here we see N^a . Thus $a \approx 1/2$ here, but the paper has $a_{\text{Article}} \approx 1$. That explains the “/2” in the following arrays.

"°. (Random  $\psi$ )"]

The angular separation of the furthest source from the region center is
11.1277°. We choose the statistics constants  $a_i$  and
 $c_i$ ,  $i = 1,2$ , for sources confined to regions with radii  $\rho = 12^\circ$ .

The formulas also depend on the number of sources, nSrc = 27.

For this sample, but with random polarization directions, the random runs give
the smallest alignment angle  $\bar{\eta}_{\min}$ ,  $\bar{\eta}_{\min}^{\text{Random } \psi} = 35.2602^\circ \pm 3.29664^\circ$ . (Random  $\psi$ )

For this sample, but with random polarization directions, the random runs give
the largest avoidance angle  $\bar{\eta}_{\max}$ ,  $\bar{\eta}_{\max}^{\text{Random } \psi} = 54.8311^\circ \pm 3.28622^\circ$ . (Random  $\psi$ )

```

5. Results using the Best Values ψ_n of the Polarization Directions

“Best” means we use the ψ_n that were listed in the catalog. We calculate the alignment function $\bar{\eta}(H)$ at the grid points H . Given the alignment function $\bar{\eta}(H)$, one can find the smallest alignment angle $\bar{\eta}_{\min}$ and the largest avoidance angle $\bar{\eta}_{\max}$ and determine the significances for the alignment and avoidance of the polarization directions.

In Sec. 6 below, we consider other values of the polarization directions that are near the best values, consistent with uncertainty σ_ψ in the measured values.

5a. The alignment function $\bar{\eta}(H)$.

Definitions:

$v\psi$ Src	unit vectors along the polarization directions in the tangent planes of the sources
eN	local unit vectors along local North
eE	local unit vectors along local East
$j\eta$ BarHj	$\{j, \bar{\eta}(H)\}$, where j is the index for grid point H_j and $\bar{\eta}(H)$ is the average alignment angle at H_j . See Eq. (1) in the Introduction.
sortj η BarHj	$\{j, \bar{\eta}(H)\}$, sorted, with smallest angles $\bar{\eta}(H)$ first.
$j\eta$ BarMin	$\{j, \bar{\eta}(H)\}$, the j and $\bar{\eta}$ for the smallest value of $\bar{\eta}(H)$, best alignment
η BarMin	the smallest value of $\bar{\eta}(H)$, measures alignment of the polarization directions

$j\eta\text{BarMax}$	$\{j, \bar{\eta}(H)\}$, the j and $\bar{\eta}$ for the largest value of $\bar{\eta}(H)$, most avoided
ηBarMax	the largest value of $\bar{\eta}(H)$, measures avoidance
$nSx\psi n$	unit vector, $S_i \times \psi_i$, cross product of the radial vector to the source with the vector in the direction of the polarization
$nSxHj$	unit vector, $S_i \times H_j$, cross product of the radial vector to the source with the radial vector to the grid point H_j
ηmHj	alignment angle between source and grid point H_j , see Fig. 1
ηBarHj	alignment angle $\bar{\eta}(H_j)$ between source and grid point H_j , averaged over all sources
$j\eta\text{BarHj}$	$\{j, \bar{\eta}(H_j)\}$, the j and $\bar{\eta}$ for grid point H_j
$\text{sig}\eta\text{BarMin}$	significance of the smallest alignment angle
$\text{sigrange}\eta\text{BarMin}$	get the range of sigs using the plus/minus values on the parameters c_i, a_i
$\text{sigSmall}\eta\text{BarMin}$	the smallest of the values in $\text{sigrange}\eta\text{BarMin}$
$\text{sigBig}\eta\text{BarMin}$	the largest of the values in $\text{sigrange}\eta\text{BarMin}$
$\text{sig}\eta\text{BarMax}$	significance of the largest alignment angle (i.e. avoidance)
$\text{sigrange}\eta\text{BarMax}$	get the range if sigs using the plus/minus values on the parameters c_i, a_i
$\text{sigSmall}\eta\text{BarMax}$	the smallest of the values in $\text{sigrange}\eta\text{BarMax}$
$\text{sigBig}\eta\text{BarMax}$	the largest of the values in $\text{sigrange}\eta\text{BarMax}$
$\alpha\text{HminDegrees}$	α of the point H_{\min} where $\bar{\eta}(H)$ is the smallest
$\delta\text{HminDegrees}$	δ of the point H_{\min} where $\bar{\eta}(H)$ is the smallest
$\alpha\text{HmaxDegrees}$	α of the point H_{\max} where $\bar{\eta}(H)$ is the largest
$\delta\text{HmaxDegrees}$	δ of the point H_{\max} where $\bar{\eta}(H)$ is the largest

The min alignment angle is $\eta_{\min} = 21.1667^\circ$, which has a significance of $\text{sig.} = 0.0000116577$, plus/minus = $+ 0.000030202$ and $- 9.01817 \times 10^{-6}$, giving a range from $\text{sig.} = 2.6395 \times 10^{-6}$ to 0.0000418597 .

The max avoidance angle is $\eta_{\max} = 66.6554$

$^\circ$, which has a significance of $\text{sig.} = 0.000195551$, plus/minus = $+ 0.000358332$ and $- 0.00013804$, giving a range from $\text{sig.} = 0.0000575103$ to 0.000553883 .

These uncertainties are due to the uncertainties in the constants c_i , a_i .

5b. Plot of the Alignment Angle Function $\bar{\eta}(H)$

Definitions

$\alpha_j \delta_j \eta \text{BarHjTable}$	$\{\alpha_j, \delta_j, \bar{\eta}(H)\}$ at each grid point $H = H_j$, in degrees
$\eta \text{BarHjSmooth}$	interpolation of $\alpha_j \delta_j \eta \text{BarHjTable}$ yields $\bar{\eta}(H)$ as a smooth function of the (α, δ) of H
$xy \eta \text{BarAitoffTable}$	$\{x, y, \bar{\eta}(x, y)\}$, where x, y are Aitoff coordinates and $\bar{\eta}(x, y)$ is the alignment angle
$xy \text{AitoffSources}$	$\{x, y\}$ Aitoff coordinates for the sources' locations on the sphere
$d\eta \text{ContourPlot}$	separation of successive contour lines, in degrees
listCP	list contour plot of $\bar{\eta}(H)$ from $xy \eta \text{BarAitoffTable}$
$\text{mapOf} \eta \text{Bar}$	contour plot of the alignment angle $\bar{\eta}(H)$, adorned with source locations and labels
$r \text{CenterSrc}$	arithmetic average of the radial unit vectors to the sources, previously called sourceCenter
rH_{\min} , rH_{\max}	radial unit vectors to the alignment and avoidance hubs H_{\min} and H_{\max}
$r \text{PerpHmin}(\text{max})$	a unit vector in the plane of the great circle combining $r \text{CenterSrc}$ and $rH_{\min}(\text{max})$
$r \text{GreatMinCircle}(\theta)$ (Max)	radial unit vector to a point on the great circle
$\alpha \text{GreatMin}(\text{Max})$	longitude at the point for θ
$\delta \text{GreatMin}(\text{Max})$	latitude at the point for θ
$xy \text{AitoffGreatMin}(\text{Max})$	Aitoff plot coordinates for the great circles
$\text{crossMin}(\text{Max})$	unit vector perpendicular, normal to the plane of the great circle
$\theta_{\min \text{MAXgreatcircles}}$	angle between the vectors normal to the planes of the two great circles

$$\text{In[]:= } r \text{CenterSrc} \theta = \frac{1}{n \text{Src}} \text{Sum}[r \text{Src}[[i]], \{i, \text{Length}[r \text{Src}]\}];$$

5c. Section Summary

This sample is an extreme case, the alignment hub H_{\min} is very close to the sources.

We include the Great Circle from the center of the sources to the alignment hub H_{\min} on the map. We also draw the Great Circle from source center to the avoidance hub H_{\max} . The two Great Circles divide the sphere quite evenly, the two Great Circles are perpendicular at the two points where they cross, within experimental error.

```

Out[]:=

Figure 5: The alignment function $\bar{\eta}(H)$, Eq. (1). The map is centered on $(\alpha, \delta) = (180^\circ, 0^\circ)$, with $\alpha = 0^\circ$ on the left and $\alpha = 360^\circ$ on the right, Equatorial Coordinates.

The sources are located at the dots, shaded ■.

The smallest alignment angle is $\bar{\eta}_{\min} = 21^\circ$, located at the alignment hubs H_{\min} and $-H_{\min}$ in the areas shaded ■.

The hubs H_{\min} and $-H_{\min}$ are located at $(\alpha, \delta) = \{188, 0\}$ and $\{8, 0\}$, in degrees.

The largest avoidance angle is $\bar{\eta}_{\max} = 67^\circ$, located at the avoidance hubs H_{\max} and $-H_{\max}$ in the areas shaded ■.

The hubs H_{\max} and $-H_{\max}$ are located at $(\alpha, \delta) = \{137, -32\}$ and at $\{317, 32\}$, in degrees.

To guide the eye, two Great Circles are plotted, one through the sources' center and the avoidance hubs H_{\max} and $-H_{\max}$. The other connects the center of the sources' locations with the alignment hubs H_{\min} and $-H_{\min}$. The Great Circles are shaded Gray, ■.

Notes: Although somewhat obscured by the distortion needed to plot a sphere on a flat surface, the function $\bar{\eta}(H)$ is symmetric across diameters. Diametrically opposite points $-H$ and H have the same alignment angle $\bar{\eta}(H)$.

```

Statistics of the Alignment Function $\bar{\eta}(H)$:

The number of sources: N = 27

The min alignment angle, $\eta_{\min} = 21.1667^\circ$, is
 14.0934° below the most likely value, 35.2602° , for random runs.

Since the uncertainty σ is 3.29664° , the difference
 14.0934° is 4.27509σ s from the most likely random run value.

Thus, the smallest alignment angle $\bar{\eta}_{\min}$ is 4.27509σ s below the most likely random run value.

The largest avoidance angle, $\eta_{\max} = 66.6554^\circ$, is
 11.8243° above the most likely value, 54.8311° , for random runs.

Since the uncertainty σ is 3.28622° , the difference
 11.8243° is 3.59814σ s from the most likely random run value.

Thus, the largest avoidance angle $\bar{\eta}_{\max}$ is 3.59814σ s above the most likely random run value.

```
In[ ]:= Print["The center of the sources is a point that makes a great circle, shaded ",
  Gray, " in Fig. 5, with the alignment hub Hmin."]
Print["The center of the sources makes a second great circle, shaded ",
  Gray, " in Fig. 5, with the avoidance hub Hmax."]
Print["The angle between the planes of the two great circles is ",
   $\theta_{\text{minMAXgreatcircles}}$ , "°."]

```

The center of the sources is a point that makes a great circle, shaded in Fig. 5, with the alignment hub H_{min} .

The center of the sources makes a second great circle, shaded in Fig. 5, with the avoidance hub H_{max} .

The angle between the planes of the two great circles is 91.1259° .

6. Uncertainty Runs

6a. Creating and Storing Uncertainty Runs

For each “uncertainty run”, the polarization direction ψ for each source is allowed to differ from the best value ψ_n by an amount $\delta\psi$ chosen according to a Gaussian distribution with mean (best) value ψ_n and half-width $\sigma\psi$, $\psi = \psi_n + \delta\psi$. Both values ψ_n and $\sigma\psi$ are taken from the catalogs.

Definitions:

$r_{\text{Src} \times \text{Grid}}$ unit vector $S_i \times H_j$ in the direction of the cross product of the radial vector S_i to a source with the radial vector H_j to a grid point

μ the mean value μ of the measurement Gaussian for ψ

σ the uncertainty of the measured polarization position angle ψ

ψ_{Data} polarization directions $\psi = \psi_n + \delta\psi$

runData collection of data to save from the uncertainty runs, see below for content list

n_{RunPrint} dummy index controlling when current TimeUsed and MemoryInUse are printed

ψ_{Src} the polarization direction ψ for the run.

$r_{\text{Src} \times \psi_{\text{Src}}}$ unit vector, $S_i \times \psi_i$, cross product of the radial vector S_i to the source with the vector \hat{v}_ψ in the direction of the polarization

$j\eta_{\text{BarToGrid}}$ $\{j, \bar{\eta}(H_j)\}$, where j is the index for the grid point H_j and $\bar{\eta}(H_j)$ is the alignment angle function, (1), at H_j

$\text{sort}j\eta_{\text{BarToGrid}}$ sort $\{j, \bar{\eta}(H_j)\}$, with the smaller angle $\bar{\eta}(H)$ first.

$j\eta_{\text{BarMin1}}$ $\{j, \bar{\eta}(H)\}$ for the smallest value of $\bar{\eta}(H)$, best alignment

$j\eta_{\text{BarMax1}}$ $\{j, \bar{\eta}(H)\}$, for the largest value of $\bar{\eta}(H)$, most avoided

$\eta_{\text{BarMinData}}$ values of $\bar{\eta}_{\text{min}}$ from uncertainty runs, alignment

$\eta_{\text{BarMaxData}}$ values of $\bar{\eta}_{\text{max}}$ from uncertainty runs, avoidance

$H_{\text{min}\alpha\text{Data}}$ values of $\alpha = \alpha$ for hub H_{min} from uncertainty runs, alignment

$H_{\text{min}\delta\text{Data}}$ values of $\delta = \delta$ for hub H_{min} from uncertainty runs, alignment

$H_{\text{max}\alpha\text{Data}}$ values of $\alpha = \alpha$ for hub H_{max} from uncertainty runs, avoidance

$H_{\text{max}\delta\text{Data}}$ values of $\delta = \delta$ for hub H_{max} from uncertainty runs, avoidance

Tables:

ψ Data entries: 1. Run # 2. ψ Src, list of polarization position angles ψ
runData entries: 1. Run # 2. $\{\bar{\eta}_{\min}, \{\alpha, \delta\} \text{ at } H_{\min}\}$ 3. $\{\bar{\eta}_{\max}, \{\alpha, \delta\} \text{ at } H_{\max}\}$

To create Uncertainty Runs, first calculate “rSrcxrGrid” and then evaluate the “For” statement in the following two cells. One can save the results with the “Put[]” statements.

Once saved, there is no need to repeat the runs. Comment out the “rSrcxrGrid” and “For” statements by enclosing each in (*comment brackets*). The data can be retrieved with the “Get” statements.

```
rSrcxrGrid1 = Table[ Cross[ rSrc[[i]], rGrid[[j]] ], {i, nSrc}, {j, nGrid}];
(*first step:  $\alpha$ w cross product, not unit vectors*)
rSrcxrGrid = Table[ rSrcxrGrid1[[i, j]] /
  (rSrcxrGrid1[[i, j]].rSrcxrGrid1[[i, j]] + 0.000001)1/2., {i, nSrc}, {j, nGrid}];
Clear[rSrcxrGrid1];
```

(*rSrcxrGrid: table of the unit vectors perpendicular to the plane
of the great circle containing the source S_i and the grid point H_j *)

```
nR = 5000; (*number of runs with the PPA  $\psi$  allowed by measurement uncertainty. *)
 $\mu = \psi n$ ;  $\sigma = \sigma \psi n$ ; runData = {};  $\psi$ Data = {}; nRunPrint = 0;
For[nRun = 1, nRun ≤ nR, nRun++,
  If[nRun > nRunPrint, Print["At the start of run ", nRun, ", the time is ",
    TimeUsed[], " seconds and the memory in use is ", MemoryInUse[], " bytes."];
    nRunPrint = nRunPrint + 500];
   $\psi$ Src = Table[RandomVariate[NormalDistribution[ $\mu$ [[i]],  $\sigma$ [[i]]]], {i, nSrc}];
  (*table of PPA angles  $\psi$  for the sources in region  $j\theta$ , in radians*)
  rSrcx $\psi$ Src = Table[ Sin[ $\psi$ Src[[i]]] eNSrc[[i]] - Cos[ $\psi$ Src[[i]]] eESrc[[i]], {i, nSrc}];
  (*table of the cross product of rSrc and vector in direction of  $\psi$ Src,
  a unit vector*) j $\eta$ BarToGrid = Table[{j, (1/nSrc) Sum[ArcCos[
    Abs[ rSrcx $\psi$ Src[[i]].rSrcxrGrid[[i, j]] ] - 0.000001 ], {i, nSrc}], {j, nGrid}];
  (*
  {grid point #, value of the alignment angle  $\eta n H_j[j]$  averaged over all sources,
  in radians}*) sortj $\eta$ BarToGrid = Sort[j $\eta$ BarToGrid, #1[[2]] < #2[[2]] &];
  (*j $\eta$ BarToGrid, {j,  $\eta_j$ }, but sorted with the smallest alignment angles first
  *)
  j $\eta$ BarMin1 = sortj $\eta$ BarToGrid[[1]]; (* {j,  $\eta_j$ }, at the grid point  $H_j$  with minimum  $\bar{\eta}$ *)
  j $\eta$ BarMax1 = sortj $\eta$ BarToGrid[[-1]]; (* {j,  $\eta_j$ },
  at the grid point  $H_j$  with maximum  $\bar{\eta}$ *) AppendTo[ $\psi$ Data, {nRun,  $\psi$ Src}];
  AppendTo[runData, {nRun, { j $\eta$ BarMin1[[2]],
    { $\alpha$ Grid [ [ j $\eta$ BarMin1[[1]] ] ],  $\delta$ Grid [ [ j $\eta$ BarMin1[[1]] ] ]}}, { j $\eta$ BarMax1[[2]],
    { $\alpha$ Grid [ [ j $\eta$ BarMax1[[1]] ] ],  $\delta$ Grid [ [ j $\eta$ BarMax1[[1]] ] ]}}] (*collect data*) ]
```

At the start of run 1, the time is 13.39 seconds and the memory in use is 214284616 bytes.

At the start of run 501, the time is 377.109 seconds and the memory in use is 231208232 bytes.

At the start of run 1001, the time is 743.218 seconds and the memory in use is 231748936 bytes.

At the start of run 1501, the time is 1096.95 seconds and the memory in use is 232297288 bytes.

At the start of run 2001, the time is 1453.58 seconds and the memory in use is 232846056 bytes.

At the start of run 2501, the time is 1810.16 seconds and the memory in use is 233394888 bytes.

At the start of run 3001, the time is 2160.5 seconds and the memory in use is 233943656 bytes.

At the start of run 3501, the time is 2513.25 seconds and the memory in use is 234492296 bytes.

At the start of run 4001, the time is 2865.47 seconds and the memory in use is 235041128 bytes.

At the start of run 4501, the time is 3217.08 seconds and the memory in use is 235589896 bytes.

Hint: You can save memory if you do not get the " ψ Data". The table ψ Data is needed to reconstruct the exact values of the runData table, but it is not needed in any following calculation.

```
SetDirectory[homeDirectory];(*Save memory space;  $\psi$ Data is not used below.*)
(*
Put[ $\psi$ Data,"20210509PsiDataClump1RA175Dec10.dat" ] (*Save a new " $\psi$ Data"*)
*)
(* $\psi$ Data=Get["20210509PsiDataClump1RA175Dec10.dat"]; *) (*Get an old " $\psi$ Data"*)
```

Hint: Saving "runData" to a file avoids the time it takes to complete the "For" statement. Make the above "For" statement into a remark so that it doesn't evaluate.

```
SetDirectory[homeDirectory];
(*
Put[runData,"20210509runDataClump1RA175Dec10.dat" ] (*Save a new "runData".*)
*)
(*
runData=Get["20210509runDataClump1RA175Dec10.dat"];
*) (*Get an old "runData".*)
```

```
In[ ]:= Print["The number of uncertainty runs is ", Length[runData], "."]
```

6d. The Effects of Uncertainty on the Locations (α, δ) of the Alignment Hubs H_{\min}

Each uncertainty run returns an alignment hub H_{\min} . In this section, we calculate the mean and standard deviation to approximate the distribution of the locations the Alignment Hubs H_{\min} .

In any one run, the analysis produces an alignment angle $\bar{\eta}$ at each grid point. There can be just one minimum alignment angle $\bar{\eta}_{\min}$, but there are two hubs, H_{\min} and $-H_{\min}$, by the symmetry across a diameter. So we collect all the hubs together by moving the $-H_{\min}$ hubs across a diameter to join the H_{\min} hubs.

Definitions

Hmin α	α in radians for H_{\min}
Hmin δ	δ in radians for H_{\min}
σ_{α} MinFit1	half-width for α uncertainty runs
α MinFit1 mean	mean for α uncertainty runs
σ_{δ} MinFit1	half-width for δ uncertainty runs

To estimate the effects of experimental uncertainty, there were 5000 uncertainty runs.

Uncertainty runs have polarization directions  $\psi = \psi_n + \delta\psi$ ,
  where  $\delta\psi$  is chosen with a normal distribution of half-width  $\sigma\psi$  about the best value  $\psi_n$ .

The uncertainty runs determine the smallest alignment angle to be  $\bar{\eta}_{\min} = 21.7226^\circ \pm 0.850515^\circ$ .

The uncertainty runs determine the largest avoidance angle to be  $\bar{\eta}_{\max} = 66.0725^\circ \pm 0.921618^\circ$ .

The uncertainty runs give the location for one of the alignment hub  $H_{\min}$  as  $(\alpha, \delta) =$ 
  {189.688, -1.392}  $\pm$  {2.20497, 2.43013}, in degrees.

The other hub,  $-H_{\min}$ , is located diametrically opposite from  $H_{\min}$ .

The uncertainty runs give the location of the avoidance hub  $H_{\max}$  as  $(\alpha, \delta) =$ 
  {144.136, -24.9252}  $\pm$  {19.6147, 13.6058}, in degrees.

The other hub,  $-H_{\max}$ , is located diametrically opposite from  $H_{\max}$ .

The uncertainty runs determine the angle  $\theta$  between
  the two grey Great Circles in Fig. 5. to be  $\theta = 92.3208^\circ \pm 3.78289^\circ$ .

The Hubs Found from the Uncertainty Runs

Out[]:=

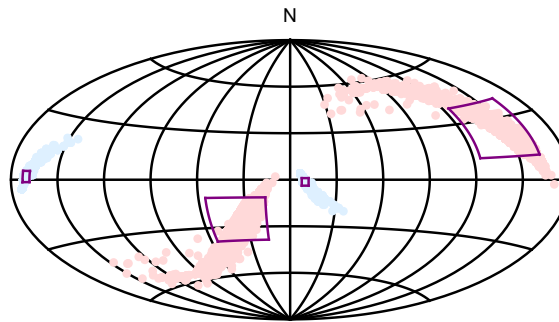

Figure 9: The 5000 sets of hubs found for the uncertainty runs.

The alignment hubs H_{\min} and $-H_{\min}$ are plotted as light blue dots, ■.

The avoidance hubs H_{\max} and $-H_{\max}$ are plotted as pink dots, ■.

The most likely locations of the hubs are outlined in purple, ■.

As a final image, we superimpose the map of the uncertainty run hubs H_{\min} , $-H_{\min}$, H_{\max} , and $-H_{\max}$ in Fig. 9 on the graph of the alignment angle function $\bar{\eta}(H)$, Fig. 5.

In[]:=

Show[{mapOf η Bar, mapOf $\sigma\psi$ HminHmax}]

Print[

"Figure 10: Overlay Fig. 9, Uncertainty Run Hubs, onto Fig. 5, Alignment Function $\bar{\eta}(H)$ using Best Values ψ_n . Note that the light blue alignment hubs from the uncertainty runs closely follow the areas of convergence (blue) for the best values ψ_n . And the pink avoidance hubs follow the areas of extreme divergence (red). One sees that shifting the polarization directions slightly due to experimental uncertainty, shifts the locations of the hubs slightly. The shifted hubs favor areas, in blue and red, that are close to the extremes for the alignment function $\bar{\eta}(H)$ in Fig.5."

The shifted hubs favor areas, in blue and red, that are close to the extremes for the alignment function $\bar{\eta}(H)$ in Fig.5.

7. Concluding Remarks

The sample of QSOs studied in this notebook has percent polarizations above 0.6%. Polarized starlight in the region is planned to be studied in some future notebook. The data shows that polarized starlight in the region of these QSOs has much lower percent polarizations, about 0.1% or so. This suggests the Milky Way contribution is small. While comparing optical and radio polarization percentages could be innately faulty, it may be that the polarization for these radio QSOs originates with the QSO upon emission or has developed enroute or some mix of the two.

By the survey in Fig. 3, one sees that very significantly aligned regions are rare with QSOs. This is unlike polarized starlight

sources in the Milky Way which has a large proportion of 5° regions well aligned, with $-\text{Log}_{10}(S)$ often over 9, when surveyed as in Fig. 3. While the percent polarization has a higher degree for QSOs compared with starlight, the significances of the alignments is generally much lower for QSOs compared with stars. It may be worthwhile to search the sky near the very significant regions, the color dots in Fig. 3, for objects that may have a polarizing effect on the radio waves from the QSOs.

If the alignment of the polarization directions of these 27 QSOs is due to some interaction with matter enroute, then the alignment hub H_{\min} being near the sources on the sky surely entails a different physical situation than with other situations having hubs that are far from the sources. When the alignment is far from the sources, all sources are polarized in more or less the same direction. A hub close to the sample on the sky, as with the 27 QSOs here, could indicate a magnetic field in different directions for the different sources, yet organized in a way that produces very significant alignment. Whatever the successful explanations are, the explanation of polarization directions aligning with nearby hubs is expected to differ in some essential ways from explanations that fit alignment characterized by near equal position angles.
