## Cantor diagonal argument-for real numbers

Richard L. Hudson 8-9-2022

## abstract

This analysis shows Cantor's diagonal argument published in 1891 cannot form a sequence that is not a member of a complete set.

## the argument

Translation from Cantor's 1891 paper [1]:
Namely, let $m$ and $n$ be two different characters, and consider a set [Inbegriff] $M$ of elements

$$
E=\left(x_{1}, x_{2}, \ldots, x_{v}, \ldots\right)
$$

which depend on infinitely many coordinates $\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{v}}, \ldots$, and where each of the coordinates is either $m$ or $w$. Let $M$ be the totality [Gesamtheit] of all elements E.
To the elements of $M$ belong e.g. the following three:

$$
\begin{aligned}
& E^{\mathrm{I}}=(\mathrm{m}, \mathrm{~m}, \mathrm{~m}, \mathrm{~m}, \ldots), \\
& \mathrm{E}^{\mathrm{II}}=(\mathrm{w}, \mathrm{w}, \mathrm{w}, \mathrm{w}, \ldots), \\
& \mathrm{E}^{\mathrm{II}}=(\mathrm{m}, \mathrm{w}, \mathrm{~m}, \mathrm{w}, \ldots) .
\end{aligned}
$$

I maintain now that such a manifold [Mannigfaltigkeit] $M$ does not have the power of the series $1,2,3, \ldots, v, \ldots$.

This follows from the following proposition:
"If $\mathrm{E}_{1}, \mathrm{E}_{2}, \ldots, \mathrm{E}_{\mathrm{v}}, \ldots$ is any simply infinite [einfach unendliche] series of elements of the manifold $M$, then there always exists an element $\mathrm{E}_{0}$ of $M$, which cannot be connected with any element $\mathrm{E}_{\mathrm{r}}$."
For proof, let there be

$$
\begin{aligned}
& \mathrm{E}_{1}=\left(\mathrm{a}_{1.1}, \mathrm{a}_{1.2}, \ldots, \mathrm{a}_{1, v}, \ldots\right) \\
& \mathrm{E}_{2}=\left(\mathrm{a}_{2.1}, \mathrm{a}_{2.2}, \ldots, \mathrm{a}_{2, \mathrm{v}}, \ldots\right) \\
& \mathrm{E}_{\mathrm{u}}=\left(\mathrm{a}_{\mathrm{u} .1}, a_{\mathrm{a} \cdot 2.2}, \ldots, \mathrm{a}_{\mathrm{u}, \mathrm{v}}, \ldots\right)
\end{aligned}
$$

where the characters $\mathrm{a}_{\mathrm{u}, \mathrm{v}}$ are either $m$ or $w$. Then there is a series $\mathrm{b}_{1}, \mathrm{~b}_{2}, \ldots \mathrm{~b}_{\mathrm{v}}, \ldots$, defined so that $\mathrm{b}_{\mathrm{v}}$ is also equal to $m$ or $w$ but is different from $\mathrm{a}_{\mathrm{v}, \mathrm{v}}$.
Thus, if $\mathrm{a}_{\mathrm{v}, \mathrm{v}}=\mathrm{m}$, then $\mathrm{b}_{\mathrm{v}}=\mathrm{w}$.
Then consider the element

$$
\mathrm{E}_{0}=\left(\mathrm{b}_{1}, \mathrm{~b}_{2}, \mathrm{~b}_{3}, \ldots\right)
$$

of $M$, then one sees straight away, that the equation

$$
\mathrm{E}_{0}=\mathrm{E}_{\mathrm{u}}
$$

cannot be satisfied by any positive integer $u$, otherwise for that $u$ and for all values of $v$.

$$
b_{v}=a_{u, v}
$$

and so we would in particular have

$$
b_{u}=a_{u, u}
$$

which through the definition of $b_{v}$ is impossible. From this proposition it follows immediately that the totality of all elements of $M$ cannot be put into the sequence [Reihenform]: $\mathrm{E}_{1}, \mathrm{E}_{2}, \ldots, \mathrm{E}_{\mathrm{v}}, \ldots$ otherwise we would have the contradiction, that a thing [Ding] E0 would be both an element of M , but also not an element of M . (end of translation)

## 1. analysis

Begin with M a random list of real numbers $>0$ and $<1$, without decimal points.
Each Eu is an infinite sequence of integers, formed from the set of ten ( 0 through 9 ). Each Eu must begin with one of those integers, and becomes a member of one of 10 subsets S0 to S9. Cantor's coordinate system u,v for row and column is used here.

## 1.1 negation

$$
\text { fig. } 1
$$

Define a diagonal form of a sequence D composed of one integer from every row after its origin. Next form a horizontal sequence E 0 that differs from D in all positions. One simple method is adding $i$ to all integers $x$ in $D$, using $x^{\prime}=(x+i) \bmod 10$. With $\mathrm{i}=1$, this assigns E0 to
subset S6. Fig. 1 shows there is nothing prohibiting the diagonal D from having a horizontal counterpart (E5). This would not be obvious since it cannot be detected with one comparison, and can occur anywhere in the list, which has no specific order of entry.

## 1.2 form

In the original list all sequences are parallel and do not interact. If the list contained all diagonal sequences as in fig.2, they would be parallel and not interact. A problem appears when the different forms are mixed as in fig.1, where E0 could not appear in any row as a horizontal sequence, since it differs in all v .

$$
\text { fig. } 3
$$

The $u, v$ coordinate system is relative to the current random list. There are many random lists. If D starts at row 11, E 0 cannot appear in any row greater than 10 but can appear in any row less than 11 as shown.
conclusion

A random list should contain sequences that are formed and entered independently of all other sequences. The transformation applies to the integers, but not the form. The diagonal form of a sequence by its extension across other sequences, prevents the appearance of its negation in any row that follows, effectively imposing a degree of order on an otherwise random list. Cantor has altered his random list to a semi random list. He forms E0 as NOT D, which assigns it to any subset except S5.
E 0 cannot occupy the same space in the list as D , and in his example D begins at $\mathrm{u}=1$, He misinterprets this as E 0 a member and not a member of M , his contradiction.
Cantor's relative comparison of D and E 0 , only shows them as members of distinct subsets, which are all members of M . All sequences in M are members of one subset and not members of the other nine subsets.
Cantor's contradiction resulted from the diagonal D , and it can be removed with the removal of D.
