# cubic ellipsoid nucleus - part 1: the model and its mass formula 

Ronen Yavor

#### Abstract

This paper examines the hypothesis that the structure of the nucleus determines that of the atom and its properties and attempts to construct a geometric model of the nucleus that contributes to this hypothesis. The model proposed here suggests that the structure of the nucleus is, in general, an ellipsoid with the nucleons connected by cubic bonds and the nucleus shells correlate with those of the atom. In accordance with the model, a simplified theoretical mass formula was created to compare it with the experimental data; the test included 82 stable nuclei from $\mathrm{Ar}_{18}^{40}$ to $\mathrm{Pb}_{82}^{210}$. The mass formula depends on two terms: - $\mathrm{E}_{\mathrm{b}}$ : the total binding energy between the nucleons in the nucleus. - $E_{c}$ : the total electric energy of the nucleus. and has two parameters: - $d_{0}$ : the minimum distance between two neighboring nucleons in the cubic structure of the nucleus. - $e_{b}$ : the binding energy between these neighboring nucleons.

The results for the calculation parameters were:

- $d_{0}=1.62 \pm 0.03 \mathrm{fm}$
- $e_{b}=5.72 \pm 0.03 \mathrm{Mev}$

The results for the relative errors of the mass formula calculation were:

| relative | maximum | average | standard dev. |
| :---: | :---: | :---: | :---: |
| error | $1.9 \%$ | $0.6 \%$ | $0.5 \%$ |

If we consider the nucleons for simplicity as rigid bodies, then we get in addition a rough estimation for $d_{0}$ through the radii of the proton and neutron:

- $\quad r_{n} \approx 0.80 \mathrm{fm}, r_{p} \approx 0.84 \mathrm{fm}, d_{0} \approx\left(r_{n}+r_{p}\right)=1.64 \mathrm{fm}$
- relative deviation of $d_{0}:\left|\frac{d_{0}-\left(r_{n}+r_{p}\right)}{\left(r_{n}+r_{p}\right)}\right| \approx 1.3 \%$

These results for the mass calculation and $d_{0}$ strengthen the model assumptions.

## The model at a glance

According to the model these are the shape and properties of the nucleus:

- the nucleus has an ellipsoid shape.
- the nucleon bonds build a cubic system.
- protons are connected to neutrons (p-n).
- neutrons are connected mainly to protons.
- the protons are populated and organized in shells in the nucleus in analogy to those of the electrons in the atom.
- the energy layers (principal quantum number $\mathbf{n}$ ) grow with the distance from the origin.
- the perpendicular distance from the $\mathbf{z}$-axis in the $\mathbf{x}$ - $\mathbf{y}$-plane reflects the angular momentum (L, sub-orbitals).
- the upper half of the ellipsoid is referred to as spin-up and the lower part as spindown.
- the nucleus possibly rotates around its $\mathbf{z}$-axis.

The following drawings describe the idea via cross sections in the $\mathbf{x - z}$-plane of the nucleus.

1: a nucleon
in the nucleus

2: the bonds between the nucleons

3: the energy levels of the nucleus

1. a nucleon (circle) is observed inside the ellipsoid (dashed line) that encloses the nucleons and schematically defines the nucleus surface:

- the distance from the origin represents its energy $\mathbf{E}$.
- the distance from the $\mathbf{z}$-axis depicts it angular momentum L .
- the nucleons in the upper half have spin-up, and in the lower one spin-down.

2. the bonds between the nucleons are shown for visibility as springs.

- protons: full circles of the s, p and dl sub-orbitals. neutrons: hollow circles.

3. the circles of equal energy states $\mathbf{n}$ in the ellipsoid.

- the lines mark the development of the $\mathbf{s}, \mathrm{p}$ and $\mathbf{d}$ sub-orbitals along the $\mathbf{z}$-axis.
- the $s$ line crosses all $\mathbf{n}$ circles from 1 to 4 ( $\mathbf{s} 1$ to $\mathbf{s 4}$ ).
- the p line begins by $\mathbf{n}=2$ and reaches till $\mathbf{n}=4$ (p2 to p4).
- the dl line begins by $\mathbf{n}=3$ and reaches the ellipsoid border, before it reaches the $\mathbf{n}=4$ circle, and therefore there are no d 4 states at this stage (only d3).

## Introduction

The nucleus and the atom are governed by different forces, have a size difference of about 5 orders of magnitude and according to current physics the order of the nucleus in shells is different than that of the atom [10].
The hypothesis, that this research investigates, is that the structure of the nucleus determines the one of the atom; therefore an attempt was made to find a geometric model that could describe this and, at the same time, meet the requirements and constraints of the current theories of nuclear and atomic physics to justify this new perspective without contradictions. The starting point was that the hypothesis holds and so, in the opposite direction, it is possible to learn and deduce from the atom about the structure of the nucleus.
Once such a model was obtained it was tested and compared with experimental data. The methods used in this work to analyze the nucleus are essentially those of classical physics.

## Requirements

The nucleus shape

- The structure of the nucleus shall "make sense" physically.
- The nuclear density (meaning the distance between two neighboring nucleons) is assumed to be (at least nearly) constant and the structure of the nuclear bonds is homogeneous and periodic.
- A proton is connected only to neutrons (p-n bond) because we assume that the p-p bond has a too strong electric repulsion; otherwise we could expect to observe a stable $\mathrm{He}_{2}^{2}$ atom for instance.
- A neutron is preferably connected with protons (p-n bond) because it is assumed that the proton stabilizes the neutron and that the $\mathbf{n}-\mathbf{n}$ bond alone (with no protons involved) is unstable; otherwise we could expect to observe a stable $\mathbf{n}-\mathbf{n}$ nucleus.

## Reflection of the atom properties

If the nucleus influences the atom, then it should reflect the atomic structure:

- the atomic energy levels or shells.
- the orbitals and sub-orbitals and their population sequence.
- the correct number of neutrons for each isotope.
- the total nuclear spin.
- Pauli's exclusion principle.
- Hund's rules of electronic states population may apply similarly to protons.

## Comparison with experimental data

- A theoretical mass formula suitable for the model shall be constructed.

## Results

## The model

We get the following model, which is developed and explained in detail below:

- The structure of the nucleus:
- the nucleus is in general an ellipsoid.
- it is composed of nucleons connected in a cubic system.
- a proton is connected to neutrons.
- a neutron is preferably connected to protons.
- the excess neutrons, beyond the number equal to that of the protons, are in the envelope of the ellipsoid.
- Properties:
- the energy levels grow with their distance from the origin. *
$\circ$ the perpendicular distance from the $\mathbf{z}$-axis (i.e. in the $\mathbf{x}$ - $\mathbf{y}$-plane) depicts the angular momentum (and so the sub-orbitals). *
- the upper side of the ellipsoid is arbitrarily defined as spin-up and the lower part as spin-down. *
- the model assumes that the nucleus possibly rotates around its main axis (the z-axis).*
- The model tries to deliver the following:
- a justification of the electron shells, the energy levels, the orbitals and suborbitals and an explanation of the structure of the atom and the periodic table.
- the right number of protons and neutrons in the nucleus and the correct nuclear spin.
- in addition:
- It doesn't contradict Pauli's exclusion principle.
- like in the atomic physics the population sequence of the protons is possibly according to Hund's rules in the range where the electronic states follow the L-S coupling.*
- Examining the model:
- the ellipsoid shape makes sense physically.
- a theoretical mass formula was created and delivered good results:
- nuclei mass with an average relative error $<1 \%$.
- combined radii of proton and neutron with a relative error $<2 \%$.

[^0]
## The Mass formula

The mass formula was developed to match the model and test its feasibility:

$$
m_{\text {calc }_{x}}=Z_{x} \cdot m_{p}+N_{x} \cdot m_{n}-\frac{\left(E_{b_{x}}-E_{c_{x}}\right)}{c^{2}}
$$

- $m_{\text {calc }}$ : the calculated mass of the nucleus x .
- $Z_{x}$ : the atomic number of the nucleus x (number of protons).
- $m_{p}$ : the mass of the proton.
- $N_{x}$ : the number of neutrons in the nucleus x (number of nucleons $A_{x}$ minus $Z_{x}$ ).
- $m_{n}$ : the mass of the neutron.
- $E_{b_{x}}$ : the total energy of the nucleon bonds in the nucleus x.
- $E_{c_{x}}$ : the total electric energy (between all protons) in the nucleus x .
- $c$ : the speed of light.

The binding energy of the nucleus is:
$E_{b_{x}}=e_{b} \cdot n_{b_{x}}$

- $e_{b}$ : the energy of a single nucleon-nucleon bond in the nucleus (assuming they are equal for all bonds in all nuclei).
- $n_{b_{x}}$ : the number of nucleon-nucleon bonds in the nucleus x .

The electric energy of the nucleus is:
$E_{c_{x}}=\frac{e^{2}}{4 \pi \epsilon_{0}} \frac{1}{d_{0}}\left\{\frac{1}{2} \sum_{i}^{Z_{x}} \sum_{j \neq i}^{Z_{x}} \frac{1}{d_{i, j}}\right\}=\frac{e^{2}}{4 \pi \epsilon_{0}} \frac{1}{d_{0}} e_{c_{x}}$ where $e_{c_{x}}:=\frac{1}{2} \sum_{i}^{Z_{x}} \sum_{j \neq i}^{Z_{x}} \frac{1}{d_{i, j}}$

- $d_{0}$ : the minimum distance between two neighboring nucleons in femtometer (assuming all nuclei have the same cubic structure and distance between their nucleons).
- $\quad d_{i, j}$ : the unitless distance between the protons of the indices $i$ and $j$ measured in multiples of $d_{0}: d_{i, j}=\sqrt{\left(x_{j}-x_{i}\right)^{2}+\left(y_{j}-y_{i}\right)^{2}+\left(z_{j}-z_{i}\right)^{2}}$
- $e_{c_{x}}$ : the unitless total electric energy of the nucleus (sum of the reciprocal distances).

The absolute relative error of the calculation for the nucleus x is:
rel_err $_{x}=\left|\frac{m_{\text {calc }_{x}-m_{\text {meas }_{x}}}^{Z_{x} \cdot m_{p}+N_{x} \cdot m_{n}-m_{\text {meas }}^{x}}}{}\right|=\left|\frac{m_{\text {calc }_{x}-m_{\text {meas }}^{x}}}{\text { mass_decect }_{x}}\right|$

- $m_{\text {meas }_{x}}$ : the measured mass of the nucleus x .
- rel_err $r_{x}$ is represented here in percentage.
- mass_defect ${ }_{x}: Z_{x} \cdot m_{p}+N_{x} \cdot m_{n}-m_{\text {meas }_{x}}$ is the mass defect of the nucleus x .

The mass formula, in this preliminary simplified form, depends thus only on the two variables:

- $e_{b}$ : the energy of a single nucleon-nucleon bond.
- $d_{0}$ : the minimum distance between two neighboring nucleons.

The implementation requires two preliminary calculation steps for all nuclei:

- Drawing the nucleus and counting the number of nucleon-nucleon bonds $n_{b_{x}}$.
- Calculating the relative total energy of the nucleus $e_{c_{x}}$ (sum of reciprocal distances).

## Results of the mass formula calculations

This section discusses the relative error of the mass formula calculation depending on the binding energy, $e_{b}$, and the distance between two neighboring nucleons, $d_{0}$, for 120 nuclei of common isotopes of elements from $L i_{3}$ to $P u_{94}$ (for several elements more than one isotope was taken). experimental data from [1].
The lighter nuclei till approximately $A r_{18}$ have larger relative errors than those of larger nuclei and are therefore shown in a different table.
The results of the mass formula calculation for 82 stable nuclei from $\mathrm{Ar}_{18}^{40}$ to $\mathrm{Pb}_{82}^{210}$ :

| maximum | average | st. dev. | $\leq 2 \%^{*}$ | $\leq 1 \%$ | $\leq 0.5 \%$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $1.9 \%$ | $0.6 \%$ | $0.5 \%$ | $100 \%$ | $81 \%$ | $58 \%$ |

* the amount of nuclei with a relative error smaller than or equal to $2 \%$.
- $e_{b}=5.72 \pm 0.03 \mathrm{Mev}$
- $d_{0}=1.62 \pm 0.03 \mathrm{fm}$
these values are within a reasonable range [5].

If we consider the nucleons for simplicity as rigid bodies, then we get a rough estimation for $d_{0}$ through the radii of the proton and neutron: $r_{n}$ [3] (Neutron radius), $r_{p}$ [4] (Proton radius): $d_{0} \approx\left(r_{n}+r_{p}\right)$.
Setting these values we get a result within a reasonable range:

- $\quad r_{n} \approx 0.80 \mathrm{fm}, r_{p} \approx 0.84 \mathrm{fm}, d_{0} \approx\left(r_{n}+r_{p}\right)=1.64 \mathrm{fm}$
- relative deviation for $d_{0}:\left|\frac{d_{0}-\left(r_{n}+r_{p}\right)}{\left(r_{n}+r_{p}\right)}\right|=\left|\frac{1.62-1.64}{1.64}\right| \approx 1.3 \%$

This estimation could strengthen the hypothesis of the model.

## Discussion of the results and conclusion

The theory of the cubic ellipsoid nucleus offers a different perspective that apparently doesn't contradict current physics, but could expand its understanding and open new research direction, not only in nuclear physics, but also in atomic and other fields.

The model aims to achieve the following:

- a tangible geometric shape for the nucleus and the connection between the structure of the nucleus and the atom.
- a reflection of the structure of the periodic table in terms of the shells, the number protons and neutrons for each isotope, and qualitatively for the energy levels and orbitals; it was built that way from the beginning, but here it was shown to be possible.
- a theoretical mass formula, that relates directly to the theory. [11]
- the mass formula calculates the nuclear masses in good agreement with the experimental data.
- the distance $d_{0}$ between two neighboring nucleons agrees with the sum of the neutron and proton radii; this strengthens the model assumption and the concept of the mass formula.
- the chemical properties of an atom are independent of its isotopes; we therefore assume that its protons have the same spatial structure for all of its isotopes; this justifies the model assumption, that the excess neutrons are located in the envelope.
- the model delivers the correct total nuclear spin.

## Remarks

- at this stage the "exact" organization of the core of the nucleus (its inner part, pairs of protons and neutrons) is known only for nuclei with complete sub-orbital, but we believe to have a good estimation also for the other nuclei.
- Light nuclei (below Argon and especially below Nitrogen) have a larger deviation from the mass formula calculation; the reason is assumed to be their structure that is not perfectly cubic or their density, meaning the distance between neighboring nucleons, that is slightly larger than their value by "well ordered" nuclei. Further research shall consider this.

## Appendix

## The development of the model

We describe in the following a visual way for the model development in order to make the idea easier to grasp.
The number of protons for closed layers of the periodic table is: $\mathbf{2}, \mathbf{8}, \mathbf{8}, \mathbf{1 8}, \mathbf{1 8}, \mathbf{3 2}, 32$.
We assume that the protons and neutrons are ordered in pairs, so the number of nucleons is:
$4,16,16,36,36,64,64$, or as square powers: $\mathbf{2}^{2}, \mathbf{4}^{2}, \mathbf{4}^{2}, \mathbf{6}^{2}, \mathbf{6}^{2}, \mathbf{8}^{\mathbf{2}}, \mathbf{8}^{\mathbf{2}}$.
We get square layers in a cubic structure placed on top of each other to form a square pyramid shape as shown in the following figure:

Legend: protons: full circles according to the orbitals S, P, D, F. neutrons: hollow circles with colors according to their orbital.
or as a table (p-protons, $\mathbf{n}$-neurons, $\mathbf{A}=\mathbf{p}+\mathbf{n}$ : nucleons):

| layer | $\mathbf{p}$ | $\mathbf{n}$ | $\mathbf{A}=\mathbf{p}+\mathbf{n}$ | $\mathbf{p}$ total | $\mathbf{A}$ total | $\mathbf{S}$ | $\mathbf{P}$ | $\mathbf{D}$ | $\mathbf{F}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{1}$ | 2 | 2 | 4 | 2 | 4 | 2 |  |  |  |
| $\mathbf{2}$ | 8 | 8 | 16 | $2+8=10$ | $16+4=20$ | 2 | 6 |  |  |
| $\mathbf{3}$ | 8 | 8 | 16 | $10+8=18$ | $20+16=36$ | 2 | 6 |  |  |
| $\mathbf{4}$ | 18 | 18 | 36 | $18+18=36$ | $36+35=72$ | 2 | 6 | 10 |  |
| $\mathbf{5}$ | 18 | 18 | 36 | $36+18=54$ | $72+36=108$ | 2 | 6 | 10 |  |
| $\mathbf{6}$ | 32 | 32 | 64 | $54+32=86$ | $108+64=172$ | 2 | 6 | 10 | 14 |
| $\mathbf{7}$ | 32 | 32 | 64 | $86+32=118$ | $172+64=236$ | 2 | 6 | 10 | 14 |

The interim result received for the noble gases is:
$H e_{2}^{4}, N e_{10}^{20}, A r_{18}^{36}, K r_{36}^{72}, X e_{54}^{108}, R n_{86}^{172}, O g_{118}^{236}$.

- The number of nucleons $\mathbf{A}$ (atomic mass) is correct for Helium and Neon.
- Argon has a stable isotope with 36 nucleons, but its most common isotope consists of 40 nucleons. [1]
- For nuclei larger than Argon the number of nucleons is larger than what we found.

Next assumption is that as the nucleus grows, excess neutrons are required to stabilize it. The model shall thus be expanded to explain the number of excess neutrons in each layer. This begins after Neon, i.e. from the third layer of the periodic table.

## Completing the nucleus layers

In order to stabilize the nucleus, excess neutrons are added from the third layer.
We demand that each layer has more neutron than its predecessor under the assumption that this increases the nucleus stability.
We receive the following pyramid shape:

Legend: protons: full circles according to the orbitals S, P, D, F. neutrons: hollow circles with colors according to their orbital. excess neutrons: beyond the number of the protons.

The number of excess neutrons for each layer is $\mathbf{0}, \mathbf{0}, \mathbf{4}, \mathbf{8}, \mathbf{1 2}, \mathbf{1 6}, 20$ respectively, meaning a total of $4,16,20,44,48,80,84$ nucleons at each layer.

| layer | $\mathbf{p}$ | $\mathbf{n}=\mathbf{p}+$ add. | $\mathbf{A}=\mathbf{p}+\mathbf{n}$ | $\mathbf{p}$ tot. | $\mathbf{A}$ total | $\mathbf{S}$ | $\mathbf{P}$ | $\mathbf{D}$ | F |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{2}$ | $2+2=4$ | 2 | 4 | 2 |  |  |  |
| $\mathbf{2}$ | 8 | $8+\mathbf{0}=8$ | $8+8=16$ | 10 | $4+16=20$ | 2 | 6 |  |  |
| $\mathbf{3}$ | 8 | $8+4=12$ | $8+12=20$ | 18 | $20+20=40$ | 2 | 6 |  |  |
| $\mathbf{4}$ | 18 | $18+8=26$ | $18+26=44$ | 36 | $40+44=84$ | 2 | 6 | 10 |  |
| $\mathbf{5}$ | 18 | $18+\mathbf{1 2}=34$ | $18+34=48$ | 54 | $84+48=132$ | 2 | 6 | 10 |  |
| $\mathbf{6}$ | 32 | $32+\mathbf{1 6}=48$ | $32+48=80$ | 86 | $132+80=212$ | 2 | 6 | 10 | 14 |
| $\mathbf{7}$ | 32 | $32+\mathbf{2 0}=52$ | $32+52=84$ | 118 | $212+84=296$ | 2 | 6 | 10 | 14 |

The results received for the noble gases are:
$H e_{2}^{4}, N e_{10}^{20}, A r_{18}^{40}, K r_{36}^{84}, X e_{54}^{132}, R n_{86}^{212}, O g_{118}^{296}$.
for the stable nuclei up to Xenon these results are correct. Radon and Oganesson are radioactive and are large. For Radon $R n_{86}^{212}$ is an isotope with a half-life in the range of minutes [1]. About Oganesson there is not much data, but $O g_{118}^{296}$ is expected to be one of its isotopes $[6,7,8]$.

## Splitting the layers to form an ellipsoid

The pyramid form is not symmetrical with respect to the nucleus center and does not fit the energy levels nor the liquid drop model; therefore, we split each layer in two, one at the positive side of the $\mathbf{z}$-axis and the other at its negative side.
This is the shape of the nucleus, that the model suggests.

Legend: protons: full circles according to the orbitals S, P, D, F. Numbers: energy levels. neutrons: hollow circles with colors according to their orbital.
excess neutrons, beyond the number equal to the protons (unpaired neutrons).

## The nuclei of the noble gases

As a result of the model structure we've reached in the last section, we can draw the nuclei of the noble gases:

Nucleus layers: cross sections in the $\boldsymbol{x}-\boldsymbol{y}$ planes along the $\boldsymbol{z}$ axis.
Legend: protons: full circles according to the orbitals S, P, D, F. Numbers: energy levels.
neutrons: hollow circles with colors according to their orbital.
excess neutrons: beyond a numb equal to the protons.

The layers and energy levels of the nuclei: a cross section in the $\boldsymbol{x}-\boldsymbol{z}$ plane.
excess neutrons, beyond a number equal to the protons, are not shown.

## The ellipsoids of the full sub-orbitals of the periodic table

In order to better understand the model, the ellipsoids of the full sub-orbitals are shown and ordered as they appear in the periodic table. The orbitals grow from left to right and the layers top to bottom; each colored arrow refers to the orbital that was filled last.

Cross sections in the $x-z$ plane of the ellipsoids of the full sub-orbitals

Legend: protons: full circles according to the orbitals S, P, D, F. Numbers: energy levels. neutrons: hollow circles with colors according to their orbital. excess neutrons, beyond a number equal to the protons, are not shown.

## The implementation of the mass formula calculation

This section explains how the number of nucleon-nucleon bonds $n_{b_{x}}$ and the relative total energy of the nucleus $e_{c_{x}}$ were calculated.

## Drawing the nucleus and counting the number of nucleon bonds $\boldsymbol{n}_{\boldsymbol{b}_{\boldsymbol{x}}}$

The counting of the number of nucleon-nucleon bonds $n_{b_{x}}$ of each nucleus was implemented by drawing all the nuclei in Excel sheets that automatically run this counting.
The sequence of the process was the following:

- First the Oganesson nucleus $O g_{118}^{294}$ is built, because this is the nucleus that closes the noble gases, meaning it has closed orbital and as such is more probable to draw it correctly according to the model.
- The nuclei with closed sub orbitals are derived from Oganesson:
- $O g_{118}^{294}$ is copied and the number of protons and neutrons is adjusted to create the next full sub-orbital nucleus below it, which is Copernicium $\mathrm{Cn}_{112}^{282}$.
- In a similar manner $\mathrm{Cn}_{112}^{282}$ is copied and Nobelium $N o_{102}^{256}$ is drawn.
- This process continues to form all the nuclei with closed sub orbitals (S, P, D, F).
- Beginning with every nucleus that closes a sub-orbital, the nuclei below it are built in a similar process to the above till the nucleus above the next closed sub-orbital is reached:
- Oganesson is copied to the next below it, which is Tennessine.
- Then Oganesson is copied to build Livermorium and so on till Nihonium is reached.
- Then a similar process is done by using the Copernicium $\mathrm{Cn}_{112}^{282}$ nucleus for all nuclei below it and above Nobelium $N o_{102}^{256}$.
- The process continues till every nucleus with a closed sub-orbital creates all the nuclei in its sub-orbital.

During this process the structure of the nuclei was analyzed and studied and ideas were developed on how to assess what configuration is more probable.
Next drawing shows the Excel sheet of Radon $R a_{86}^{222}$ (only the left half, spin-up, is shown due to its large size).

Legend: protons ( $\boldsymbol{p}$ ) of the orbitals S, P, D, F. neutrons (n).

## Calculating the relative total energy of the nucleus $\boldsymbol{e}_{\boldsymbol{c}_{x}}$

We first build an Excel sheet that calculates the sum of all proton-proton relative energies for Oganesson (the reciprocal distances):

$$
e_{c_{x}}=\frac{1}{2} \sum_{i}^{Z_{x}} \sum_{j \neq i}^{Z_{x}} \frac{1}{d_{i, j}} \quad \text { with } \quad \frac{1}{d_{i, j}}=\frac{1}{\sqrt{\left(x_{j}-x_{i}\right)^{2}+\left(y_{j}-y_{i}\right)^{2}+\left(z_{j}-z_{i}\right)^{2}}}
$$

then in a somewhat similar manner to the process of creating the Excel sheets that count $n_{b_{x}}$, as described in the section above, the closed sub-orbitals are created and each of them creates the nuclei in its sub-orbital below it.
Following drawings show the minimum distance between two neighboring nucleons $d_{0}$ through cross sections of the nucleus (marked by arrows in several positions):

The Excel sheet of $Y b_{70}$ explains the calculation of the relative electric energy $e_{c_{x}}$ (the reciprocal distances):

The coordinates of each proton appear once above and once from left; for each pair of (different) protons the relative electric energy (their reciprocal distance) is calculated at the point of their intersection.

## Executing the mass formula calculation; analyzing and learning the model

The exact structure of the nucleus is crucial for the study of the model and for the correct execution of the mass formula. This structure determines:

- $n_{b_{x}}$ : the number of bonds in the nucleus.
- $e_{x}$ : the total electric energy of the nucleus.

The electric energy, $e_{x}$, is less sensible towards small changes of the nucleus structure, but for $n_{b_{x}}$ small variations result in a large impact (of one percent or more) on the relative error of the mass formula calculation, so while running the tests the "correct" value of $n_{b_{x}}$ for each nucleus was sought. "Correct" means logical in the physical sense and compared with other nuclei, so this isn't something that can be proved yet by this paper. The process of filling up the nucleus with nucleon runs as follows:

- The following nuclei are selected to begin with:
- nuclei of filled-up sub-orbitals (S, P, D, F) because their real shape is assumed to be more probable to be created correctly: $B e_{4}, N e_{10}, M g_{12}, A r_{18}, C a_{20}, Z n_{30}, K r_{36}, S r_{38}, C d_{48}, X e_{54}, B a_{56}, Y b_{70}$, $H g_{80}, R n_{86}, R a_{88}$ (Hydrogen and Helium are not discussed in this paper due to their small number of bonds, that seem to deviate from the cubic structure; a separate future research shall deal with them).
- The nuclei are filled up with:
- the protons: there is only one possible configuration.
- the paired neutrons: also here there is only one possible configuration.
- the excess neutrons are set in a way that reaches maximum symmetry and compared between various nuclei to assess the probable configuration.
- The mass formula is calculated and the best parameters are found.
- The nuclei that show larger deviation of their relative errors are checked again and their structure is being studied and possibly changed via comparison with other nuclei.
- At a second step all other nuclei are being created and the process repeats itself.

After creating all nuclei, trials are run in iterations with the construction of the nuclei. This process is delicate, because we shall avoid the tendency to adapt the structure so that better results are achieved.
The results are not necessarily accurate as we cannot be sure of the correct structure of the nuclei, but a rough estimation seems possible.

## Mass formula calculation: data

This section shows the data according to which the mass of the nuclei was calculated via the mass formula.
The parameters with which the mass formula are shown here are those of the best results achieved while running the calculation:

- $d_{0}=1.62 \mathrm{fm}$
- $e_{b}=5.72 \mathrm{Mev}$

The legend of the table below is given in the order of the columns from left to right:

- nuc: the nucleus (name)
- $Z_{x}$ : atomic number of the nucleus of the element x . the number of protons.
- $A_{x}$ : mass number of the nucleus of the element x . The number of nucleons.
- $N_{x}:=A_{x}-Z_{x}$ : the number of neutrons of the nucleus of the element x .
- $n_{k}$ : the number of nucleon-nucleon bonds in the nucleus as it was calculated by the relevant Excel file. *
- $e_{c}$ : total relative electric energy of the nucleus as it was calculated by the relevant Excel file. *
- meas. [amu]: measured mass of the nucleus in [amu].
- Base: $Z_{x} \cdot m_{p}+N_{x} \cdot m_{n}$ [amu]: base mass in [amu]:
number of protons $\cdot$ proton mass + number of neutrons $\cdot$ neutron mass
- calc. $m$ [amu]: calculated mass according to the mass formula in [amu]

$$
m_{\text {calc }_{x}}=Z_{x} \cdot m_{p}+N_{x} \cdot m_{n}-\frac{\left(E_{b_{x}}-E_{c_{x}}\right)}{c^{2}} .
$$

- $\Delta_{I}:$ [amu] calc. - meas.: calculated mass - measured mass in [amu]
- $\Delta_{2}$ : [amu] base - meas.: base mass - measured mass in [amu]
- rel. err. $\Delta_{l}$ : $\Delta_{2}$ : the relative error in percent:
rel.err $=\frac{\text { calculated mass-measured mass }}{\text { base mass-measured mass }}$
