# Collatz Conjecture Proved Ingeniously \& Very Simply 

## A. A. Frempong <br> Abstract

Collatz conjecture states that beginning with a positive integer, if one repeatedly performs the following operations to form a sequence of integers, the sequence will eventually reach the integer one; the operations being that if the integer is even, divide it by 2 , but if the integer is odd, multiply it by 3 and add one; and also, use the result of each step as the input for the next step. To prove Collatz conjecture, one would apply a systematic observation of the sequences produced by the Collatz process, the $(3 n+1) \frac{1}{2}$ process, Two main cases are covered. In Case 1 , the integer can be written as a power of 2 as $2^{k}(k=1,2,3, \ldots)$, and in this case, the sequence will reach the integer 1 by repeated division by 2 , i.e., $2^{k}, 2^{k-1}, 2^{k-2}, 2^{k-3}, \ldots .2^{k-k}$. In Case 2 , the integer cannot be written as a power of 2 , but the sequence terms of the integers reach integers equivalent to $2^{2 k}(k=2,3, \ldots)$, and by repeated division by 2 , the sequences will reach the integer 1 , i.e., $2^{2 k}, 2^{2 k-1}, 2^{2 k-2}, 2^{2 k-3}, \ldots, 2^{2 k-2 k}$. In Case 2 , when the sequence terms reach some particular odd integers such as 5,21 and 85 , the application of $3 n+1$ operation to these integers will result in the integers equivalent to the powers, $2^{2 k}(k=2,3, \ldots)$. One would call these integers, the 2 k -power converters. There are infinitely many power converters as there are $2^{2 k}$ powers. A term of the sequence must be converted to an integer equivalent to $2^{2 k}(k=2,3, \ldots)$. There are infinitely many paths for converting integers to $2^{2 k}(k=2,3, \ldots)$ powers on the $2^{2 k}$-route, a route on which a $2^{2 k}$-power can be divided repeatedly by 2 until the sequence reaches the integer 1 . Of these conversion paths, the integer 5-path is the nearest $2^{2 k}(k=2)$ converter path to the integer 1 on the $2^{2 k}$-route. Other paths to the $2^{2 k}$-route include the 21 -path, $(\mathrm{k}=3)$, and the 85 -path, $(\mathrm{k}=4)$, For the 5 -path, when a sequence terms reach the integer, 5 , the next term would be $3(5)+1=16$. Similarly, for the integers 21 , and 85 , the next terms, respectively, would be $3(21)+1=64$, $3(85)+1=256$. Some non-2k power converters can follow the integer 5 -path to the $2^{4}$ power as follows: Let $n$ be an integer whose sequence terms would reach 16 or $2^{4}$ in the $(3 n+1) \frac{1}{2}$ process, and let $n \pm r=5$, where $r$ is the net change in the sequence terms before the integer 5 ; and one uses the positive sign if $n<5$, but the negative sign if $n>5$. One will call the following, the 5path 2 k -converter formula, $3(n \pm r)+1=16$. The integers $2^{p}(5)(p=1,2,3, \ldots)$ will take the integer 5-path to convert to a 2 k -power. Similar definitions and formulas for the 21-path, and the 85-path, are as follows: For the 21-path: $n \pm r=21$, The 21-path 2 k -converter formula is $3(n \pm r)+1=64$. For the 85-path: $n \pm r=85$. The 85-path 2 k -converter formula is $3(n \pm r)+1=256$. There are similar definitions and formulas for the other infinite paths. The integers, $2^{p}(21), 2^{p}(85)$ with ( $p=1,2,3, \ldots$ ), will take, respectively, the integer 21-path, and the 85 -path, to reach 2 k -powers. Just as there are infinitely many positive integers, there are infinitely many $2^{2 k}$-power converters, 2 k -powers, 2 k -power converter paths, and descendants, $2^{p} C(p=1,2,3, \ldots)$ of C . With all the above functioning together, the sequence of every positive integer that cannot be written as a power of 2 , would reach the equivalent integer, $2^{2 k}$ and by repeated division by 2 , the sequence would reach the integer 1 . Therefore, using the approaches in Cases 1 and 2, above, the sequence of every positive integer would eventually reach the integer 1 .

## Net Change

(Sum of both the pluses and minuses as in Example 2, below) Let $n$ be an integer whose sequence would reach 16 or $2^{4}$ in the $(3 n+1) \frac{1}{2}$ process and let $n \pm r=5$, where $r$ is the net change in the sequence terms before the integer 5 ; and one uses the positive sign if $n<5$ but the negative sign if $n>5$.
Example 1: Let $n=12$ with the sequence terms $12,6,3,10,5$. From 12 to 6 , the change is -6 ; from 6 to 3 , the change is -3 ; from 3 to 10 , the change is +7 ; and from 10 to 5 , the change is -5 , The net change, $r=-6-3+7-5=-7$; and $n \pm r=12-7=5$. Note: The negative sign confirms the rule of signs above. i.e., $n>5(12>5)$. Note: Since $3(5-0)+1=16,3(12-7)+1=16$, Also, $3(3+2)+1=16$, Suppose, one wants the sequence for the integer, 27 to reach 16 . Then $3(27-22)+1=16$, since $27-22=5-0$. One confirms the " $-22 "$ in $3(27-22)+1=16$, below. Example 2: Confirmation of the net change for Collatz sequence for the integer 27 Read from top to bottom in the first column, and continue from top of the next column down and repeat the process for the other columns. Numbers with " + " signs are for the positive changes, and numbers with "-" signs are for the negative changes.. .

Sum of the pluses, " + " $=40,552$.; Sum of the minuses, " - " $=-40,574$.
Sum of the pluses and the minuses $=40,552-40574=\mathbf{- 2 2}$
The net change, $r=-22$, and $n-r=27-22=5$
Example 2 confirms that one can write the net change without the tedious addition of pluses and minuses in the above table. For example, for the integer, 33, $n-r=33-28=5$.
For the integer, 45, $n-r=45-40=5$ One will call the following, the 5 -path 2 k -converter formula: $3(n \pm r)+1=16$. Using this formula, the sequence of some positive integers which cannot be written as a power of 2 , can reach the integer, 16 . Once the sequence reaches 16 , applying repeated division by 2 , the sequence will reach the integer 1 . $(16,8,4,2,1)$.

## Option 2 Introduction

## Back to Options

To prove Collatz conjecture, one would be guided by a systematic observation of the sequences produced by the Collatz process, $(3 n+1) \frac{1}{2}$ process, and note the patterns of the sequence terms as the process reaches integers equivalent to $2^{2 k}(k=2,3, \ldots)$ and continue straightforwardly as $2^{2 k}, 2^{2 k-1}, 2^{2 k-2}, 2^{2 k-3}, \ldots, 2^{2 k-2 k}$, reaching the integer 1 . For example, $2^{4}$ continues as $2^{4}, 2^{3}, 2^{2}, 2^{1}$, to $2^{0}(16,8,4,2$. to 1$)$. If an integer is equivalent to the form $2^{k}(k=1.2 .3, \ldots$,$) , by$ repeated division by 2 , the sequence would reach the integer 1 . In the numerical sequences of positive integers, in the preliminaries (Option 1), the following observations were made:
Case 1: If the integer can be written as a power of 2 as $2^{k}(k=1,2,3, \ldots)$ the sequence would reach the integer one by repeated division by 2 , i.e., $2^{k}, 2^{k-1}, 2^{k-2}, 2^{k-3}, \ldots .2^{k-k}$.
Example1: $8=2^{3}$, and $2^{3}, 2^{2}, 2^{1}, 2^{0}$ or $8.4,2,1$.
Example 2: $16=2^{4}$, and $2^{4}, 2^{3}, 2^{2}, 2^{1}, 2^{0}$ or $16,8 \cdot 4,2,1$.
Case 2 The integer cannot be written as a power of 2, but the sequence terms of this integer reach the equivalent power, $2^{2 k}(k=2,3, \ldots)$ which will continue as $2^{2 k}, 2^{2 k-1}, 2^{2 k-2}, 2^{2 k-3}, \ldots, 2^{2 k-2 k}$. In particular, if the sequence reaches the integer, 16 , the previous term would be the integer 5 . This observation is from the sequences of the first 100 positive integers, except for about five integers and the equivalent $2^{k}(\mathrm{k}=1,2,3, \ldots)$-power forms such as 8,16 , and 64 . In Case 2 , when the sequence terms reach some particular odd integers such as 5,21 and 85 , the application of $3 n+1$ operation to these integers will result in the integers equivalent to the powers, $2^{2 k}(k=2,3, \ldots)$. One would call these integers, the 2 k -power converters. There are infinitely many 2 k -power converters as there are $2^{2 k}$ powers. A term of the sequence must be converted to an integer equivalent to $2^{2 k}(k=2,3, \ldots)$. There are infinitely many paths for converting integers to $2^{2 k}(k=2,3, \ldots)$ powers on the $2^{2 k}$-route, a route on which a $2^{2 k}$-power can be divided repeatedly by 2 until the sequence reaches the integer 1 . Of these conversion paths, the integer 5-path is the nearest $2^{2 k}(k=2)$ converter path to the integer 1 on the $2^{2 k}$-route. Other paths to the $2^{2 k}$-route include the 21-path, $(\mathrm{k}=3)$, the 85 -path, $(\mathrm{k}=4)$, and the 341-path $(\mathrm{k}=5)$. For the 5 -path, when a sequence terms reach the integer, 5 , the next term would be $3(5)+1=16$. Similarly, for the integers 21,85 , and 341 , the next terms, respectively, would be $3(21)+1=64,3(85)+1=256$ and $3(341)+1=1024$. Non-2k power converters can follow the integer 5-path to the $2^{4}$ power as follows: Let $n$ be an integer whose sequence terms would reach 16 or $2^{4}$ in the $(3 n+1) \frac{1}{2}$ process, and let $n \pm r=5$, where $r$ is the net change in the sequence terms before the integer 5; and one uses the positive sign if $n<5$, but the negative sign if $n>5$. One will call the following, the 5-path 2 k -converter formula, $3(n \pm r)+1=16$. The integers with factors $2^{p}(5)(p=1,2,3, \ldots)$ would take the integer 5-path to convert to a 2 k -powers. Similar definitions and formulas for the 21-path, the 85-path and the 341-path are as follows: For the 21path: $n \pm r=21$, The 21-path 2k-converter formula is $3(n \pm r)+1=64$. For the 85-path: $n \pm r=85$, The 85 -path 2 k -converter formula is $3(n \pm r)+1=256$. For the 341-path: $n \pm r=341$, The 341path 2 k -converter formula is $3(n \pm r)+1=1024$ There are similar definitions and formulas for the other infinite number of paths.

## Option 3

## Back to Options

## Collatz Conjecture Proved Ingeniously \& Very Simply

Given: 1. A positive integer, $n$
2. The function $f(n)=\left\{\begin{array}{l}\frac{n}{2} \text { if } n \text { is even } \\ 3 n+1 \text { if } n \text { is odd }\end{array}\right.$

Required: Begin with the positive integer, $n$, and form a sequence by applying the above operation repeatedly, using the result of each step as input for the next step and prove or convince the reader that eventually, the sequence reaches the integer 1.

Plan: Write the positive integer as a power of 2 or change a term of the sequence to an integer which can be written as a power of 2 .

## Proof

Case 1: If the integer can be written as a power of 2 as $2^{k}(k=1,2,3, \ldots)$ the sequence would reach the integer one by repeated division by 2 , i.e., $2^{k}, 2^{k-1}, 2^{k-2}, 2^{k-3}, \ldots 2^{k-k}$.

Case 2: The integer cannot be written as a power of 2 , but the sequence terms of this integer reach the equivalent power, $2^{2 k}(k=2,3, \ldots)$ which will continue as $2^{2 k}, 2^{2 k-1}, 2^{2 k-2}, 2^{2 k-3}, \ldots, 2^{2 k-2 k}$.
In Case 2, (see Fig.1 on p.9) when the sequence terms reach some particular odd integers such as 5,21 and 85 , the application of $3 n+1$ operation to these integers will result in the integers equivalent to the powers, $2^{2 k}(k=2,3, \ldots)$. One would call these integers, the 2 k -power converters. There are infinitely many 2 k -power converters as there are $2^{2 k}$ powers. A term of the sequence must be converted to an integer equivalent to $2^{2 k}(k=2,3, \ldots)$. There are infinitely many paths for converting integers to $2^{2 k}(k=2,3, \ldots)$ powers on the $2^{2 k}$-route, a route on which a $2^{2 k}$-power can be divided repeatedly by 2 until the sequence reaches the integer 1 . Of these conversion paths, the integer 5-path is the nearest $2^{2 k}(k=2)$ converter path to the integer 1 on the $2^{2 k}$-route. Other paths to the $2^{2 k}$-route include the 21 -path, $(\mathrm{k}=3)$, the 85 -path, $(\mathrm{k}=4)$, and the 341 -path ( $k=5$ ). For the 5 -path, when a sequence terms reach the integer, 5 , the next term would be $3(5)+1=16$. Similarly, for the integers 21,85 , and 341 , the next terms, respectively, would be $3(21)+1=64,3(85)+1=256$ and $3(341)+1=1024$. Non- 2 K power converters can follow the integer 5-path to the $2^{4}$ power as follows: Let $n$ be an integer whose sequence terms would reach 16 or $2^{4}$ in the $(3 n+1) \frac{1}{2}$ process, and let $n \pm r=5$, where $r$ is the net change in the sequence terms before the integer 5; and one uses the positive sign if $n<5$, but the negative sign if $n>5$. One will call the following, the 5-path 2 k -converter formula, $3(n \pm r)+1=16$. The integers with factors $2^{p}(5)(p=1,2,3, \ldots)$ would take the integer 5 -path to convert to a 2 k -power. Similar definitions and formulas for the 21-path, the 85-path and the 341-path are as follows: For the 21path: $n \pm r=21$, where $r$ is the net change before the integer 21 ; and one uses the positive sign if $n<21$, but the negative sign if $n>21$. The 21-path 2 k -converter formula is $3(n \pm r)+1=64$. For the 85-path: $n \pm r=85$, where $r$ is the net change before the integer 85 ; and one uses the positive sign if $n<85$, but the negative sign if $n>85$. The 85 -path 2 k -converter formula is $3(n \pm r)+1=256$. For the 341-path: $n \pm r=341$, where $r$ is the net change before the integer 341;
and one uses the positive sign if $n<341$, but the negative sign if $n>341$. The 341-path 2kconverter formula is $3(n \pm r)+1=1024$. There are similar definitions and formulas for the other infinite number of paths. The integers with the factors, $2^{p}(21), 2^{p}(85), 2^{p}(341)$ with $(p=1,2,3, \ldots)$, will take, respectively, the integer 21 -path, the 85 -path and the integer 341 -path to reach 2 k powers. To generalize the 2 k -power conversions, let C be a 2 k -power converter such that $3 C+1=2^{2 k} \quad(k=2,3,4, \ldots)$, Also, let $2^{p} C(p=1,2,3, \ldots)$ be descendants of C. Then, the integer $2^{p}(5)(p=1,2,3, \ldots)$ will take the integer 5-path to convert to a 2 k -power. Similarly, the integers $2^{p}(21), 2^{p}(85)$ and $2^{p}(341)$ with $(p=1,2,3, \ldots)$ would take, respectively, the integer 21-path, the integer 85 -path, and the integer 341-path to convert to 2 k -powers. With infinitely many positive integers, infinitely many $2^{2 k}$-power converters, infinitely many 2 k -powers, infinitely many 2 k power converter paths, and infinitely many descendants, $2^{p} C$ ( $p=1,2,3, \ldots$ ) of C, a 2k-power converter, all with corresponding definitions, and formulas, the sequence of every positive integer that cannot be written as a power of 2 , would reach the integer, $2^{2 k}(k=2,3, \ldots)$ and by repeated division by 2 , the sequence would reach the integer 1 . Therefore, using the approaches in Cases 1 and 2 , the sequence of every positive integer would eventually reach the integer 1.

## Option 4

## Discussion

Example for integer 84 using the 21-path to reach the power, $2^{6}$
For the integer $2^{p} C$,
If $p=2, C=21$
$2^{2}(21)=84$
For the sequence, 84,42,21, $3(21)+1=64=2^{6}$
That is, the sequence of the integer 84 reached $2^{6}$ power using the 21-path.

It is worth noting that the integers, 1 quadrillion, 1 trillion, 1 billion, and 1 million, all, use the integer 5-path to convert to the 2 k -power forms

## Option 5 Conclusion

## Back to Options

By applying a systematic observation of the sequences produced by the Collatz process, the $(3 n+1) \frac{1}{2}$ process, the author has shown that Collatz conjecture is true. Particularly, one noted the patterns of the sequence terms as the process reaches the equivalent powers, $2^{2 k}(k=2,3, \ldots)$ and continues straightforwardly as $2^{2 k}, 2^{2 k-1}, 2^{2 k-2}, 2^{2 k-3},, \ldots, 2^{2 k-2 k}$. The approach used consists of two main cases, namely, Case 1 and Case 2. In Case 1, the integer can be written as a power of 2 as $2^{k}(k=1,2,3, \ldots)$, and the sequence would reach the integer one by repeated division by 2 , i.e., $2^{k}, 2^{k-1}, 2^{k-2}, 2^{k-3}, \ldots 2^{k-k}$. In Case 2 , the integer cannot be written as a power of 2 , but the sequence terms of the integer reach the equivalent power, $2^{2 k}(k=2,3, \ldots)$, and by repeated division by 2 , the sequence will reach the integer 1 , i.e., $2^{2 k}, 2^{2 k-1}, 2^{2 k-2}, 2^{2 k-3}, \ldots, 2^{2 k-2 k}$. Thus the sequence will definitely continue to 1 . when the sequence terms reach some particular integers such as 5,21 and 85 , the application of $3 n+1$ to these integers would result in integers equivalent to the powers, $2^{2 k}(k=2,3, \ldots)$. One would call these integers, the 2 k -power converters. Examples of the converters are 5,21 , and 85 with the respective $2^{2 k}$ - powers, $2^{4}, 2^{6}$, and $2^{8}$. There are infinitely many power converters as there are infinitely many $2^{2 k}$ powers. A term of the sequence of a positive integers must be converted to $2^{2 k}(k=2,3, \ldots)$ power. There are infinitely many paths for converting integers to $2^{2 k}(k=2,3, \ldots)$ powers. Of these conversion paths, the integer 5-path, is the nearest $2^{2 k}(k=2)$ converter path to the integer 1 on the $2^{2 k}$-route. For the 5 -path, when a sequence terms reach the integer, 5 , the next term would be $3(5)+1=16$ or $2^{4}$. Similarly, for the 2 k -power converter, 21 , the next term would be $3(21)+1=64=2^{6}$. Some other integers, can follow the integer 5-path to the $2^{4}$ power as follows: Let $n$ be a descendant of 5 and let $n \pm r=5$, where $r$ is the net change in the sequence terms before the integer 5 ; and one uses the positive sign if $n<5$, but the negative sign if $n>5$. One will call the following, the 5 -path 2 k -converter formula: $3(n \pm r)+1=16$ or $2^{4}$. By the substitution axiom, using this formula, the sequence of some positive integers, that cannot be written as a power of 2 , would reach the integer, 16 , as in Case 2; and once the sequence reaches 16 , by repeated division by 2 , the sequence would reach the integer 1 . The integers with factors $2^{p}(5)(p=1,2,3, \ldots)$ would take the integer 5 -path to convert to a 2 k -power. In Case 1 , the integer can be written as a power of 2 as $2^{k}(\mathrm{k}=1,2,3, \ldots)$; and the sequence will reach the integer 1 , by repeated division by 2 , i.e., $2^{k}, 2^{k-1}, 2^{k-2}, 2^{k-3}, \ldots 2^{k-k}$. Just as there are infinitely many positive integers, there are infinitely many $2^{2 k}$-power converters, infinitely many 2 k -powers, infinitely many 2 k -power converter paths, and infinitely many descendants, $2^{p} C$ ( $p=1,2,3, \ldots$ ) of $C$, and with all the above functioning together, the sequence of every positive integer that cannot be written as a power of 2 , would reach the equivalent power, $2^{2 k}$. By repeated division by 2 , the sequence would reach the integer 1 . Therefore, using the approaches in Cases 1 and 2, the sequence of every positive integer would eventually reach the integer 1. The approach used in this paper has applications in civil engineering, especially in road design and construction as well as town and country planning.

## Option 6 Integer Humor

Integer 5 speaks: Integer 27, the integer 21-path is near you. Why did you not use the 21-path to cross to the $2^{2 k}$-route, but instead, you went through the jungle to use my path?

Integer 27 answers: I am not a descendant of integer 21, For me to use the 21-path my name should be $(21) 2^{p}(p=1,2, \ldots)$. Perhaps, when I reached the entrance to the 21path, the Kamikaze typhoon blew me away to your path.
Integer 84 speaks
to Integer 21: What should I write on the path formula if I want to use your path to go to the $2^{2 k}$-route?
Integer 21 answers: Write $3(84-63)+1=64=2^{6}$ on the formula.

## Integer 21 speaks

to Integer 32:
Integer 32, When are you going to use my path to cross to the $2^{k}, 2^{2 k}$-route?
Integer 32 answers: I, $2^{5}$, do not need to use your path. I am already on the $2^{k}, 2^{2 k}$-route, and I am on my way to attend the UN meeting on 1st Avenue,

## Adonten
