# No Collatz Conjecture integer series have looping <br> Tsuneaki Takahashi 

#### Abstract

If the series of Collatz Conjecture integer has looping in it, it is sure the members of the loop cannot reach to value 1 . Here it is proven that the possibility of looping is zero except one.

## 1. Introduction

Procedure of Collatz Conjecture is recognized as following operations.
It starts with positive odd integer $n_{1}$.
It continues following calculation up to $n_{i}=1$.

- Compute $n=3 \times n_{i-1}+1$.
- $n$ is divided by 2 , $m_{i-1}$ times until it becomes positive odd integer.

$$
\begin{equation*}
n_{i}=\frac{n}{2^{m_{i-1}}} \tag{2}
\end{equation*}
$$

## 2. Looping

Collatz conjecture procedure is represented as follow.

$$
\begin{align*}
& \left(3\left(\left(3\left((3 \times n+1) / 2^{m_{1}}\right)+1\right) / 2^{m_{2}}\right)+1\right) / 2^{m_{3}} \cdots \\
& =\frac{3^{i} n}{2^{m_{1}+m_{2}+\cdots+m_{i}}}+\frac{3^{i-1}}{2^{m_{1}+m_{2}+\cdots+m_{i}}}+\frac{3^{i-2}}{2^{m_{2}+\cdots+m_{i}}}+\cdots+\frac{3^{1}}{2^{m_{i-1}+m_{i}}}+\frac{3^{0}}{2^{m_{i}}} \tag{3}
\end{align*}
$$

n : starting positive odd integer
If this procedure has looping, following equation is satisfied.

$$
\begin{align*}
& \frac{3^{i} n}{2^{m_{1}+m_{2}+\cdots+m_{i}}}+\frac{3^{i-1}}{2^{m_{1}+m_{2}+\cdots+m_{i}}}+\frac{3^{i-2}}{2^{m_{2}+\cdots+m_{i}}}+\cdots+\frac{3^{1}}{2^{m_{i-1}+m_{i}}}+\frac{3^{0}}{2^{m_{i}}}=n .  \tag{4}\\
& \left(2^{m_{1}+m_{2}+\cdots+m_{i}}-3^{i}\right) n=3^{i-1}+2^{m_{1}} \cdot 3^{i-2}+\cdots+2^{m_{1}+m_{2}+\cdots+m_{i-2}} \cdot 3^{1}+2^{m_{1}+m_{2}+\cdots+m_{i-1}} \cdot 3^{0} . \tag{5}
\end{align*}
$$

Characteristics of right side (5) are followings.
It is expanded using power of 3 from $3^{0}$ to $3^{i-1}$ term.
Coefficient for each power of 3 is represented as one bit of binary
(ex. $2^{m_{1}+m_{2}+\cdots+m_{i-2}}$ ), also each power of 3 and its coefficient has following relation.

$$
\begin{equation*}
2^{m_{1}+m_{2}+\cdots+m_{i-j} \cdot 3^{j-1}} \quad j: \text { integer, } 1,2,3 \cdots \cdots, m_{0}=0 . \tag{b}
\end{equation*}
$$

Existence of positive odd integer n solution for (5) means that there is looping.
We investigate whether such n solution could exist or not.
Left side of (5) could be expanded and become same format as right side. (6) defines $m$ for $i t$.

$$
\begin{equation*}
\mathrm{m}=\left(m_{1}+m_{2}+\cdots+m_{i}\right) / i \tag{6}
\end{equation*}
$$

Left side of (5) becomes (7).

$$
\begin{equation*}
\left(2^{m i}-3^{i}\right) n=\left(2^{m}-3\right)\left(3^{i-1}+2^{m} \cdot 3^{i-2}+\cdots+2^{m(i-2)} \cdot 3^{1}+2^{m(i-1)} \cdot 3^{0}\right) n \tag{7}
\end{equation*}
$$

Then (5) becomes (8).

$$
\begin{align*}
& \left(2^{m}-3\right)\left(3^{i-1}+2^{m} \cdot 3^{i-2}+\cdots+2^{m(i-2)} \cdot 3^{1}+2^{m(i-1)} \cdot 3^{0}\right) n \\
& \quad=3^{i-1}+2^{m_{1}} \cdot 3^{i-2}+\cdots+2^{m_{1}+m_{2}+\cdots+m_{i-2}} \cdot 3^{1}+2^{m_{1}+m_{2}+\cdots+m_{i-1}} \cdot 3^{0} \tag{8}
\end{align*}
$$

Both sides (8) have following form.

$$
\begin{aligned}
& \sum_{i=0}^{i-1} \alpha_{i} p^{i} \\
& \quad \alpha_{i} ; \text { These have } n \\
& \quad i ; 0,1,2, \ldots \ldots \\
& \quad p ; \text { integer }(=3)
\end{aligned}
$$

$$
\alpha_{i} ; \text { These have no element of } p \text { or } \frac{1}{p}
$$

No term $\alpha_{n} p^{n}$ of left side cannot be represented by linear combination of right-side terms which have power of $p$ other than $n$, that is,

$$
\begin{equation*}
\alpha_{n} p^{n} \neq \sum_{i=0}^{i \neq n} \beta_{i} p^{i} \tag{11}
\end{equation*}
$$

## Proof is;

In the case $i<n$, its form is,

$$
\begin{equation*}
\sum_{i=0}^{n-1} \beta_{i} p^{i}=\left(\beta_{0} \frac{1}{p^{n}}+\beta_{1} \frac{1}{p^{n-1}}+\cdots+\beta_{n-1} \frac{1}{p^{1}}\right) p^{n} \tag{12}
\end{equation*}
$$

In the case $i>n$, its form is,

$$
\begin{equation*}
\sum_{i=n+1}^{i} \beta_{i} p^{i}=\left(\beta_{n+1} p^{1}+\beta_{n+2} p^{2}+\cdots\right) p^{n} \tag{13}
\end{equation*}
$$

Here each term (12) has $\frac{1}{p}$ and each term (13) has $p$
Therefore, in the total case of $i \neq n$,

$$
\begin{equation*}
\sum_{i=0}^{i \neq n} \beta_{i} p^{i}=\left(\beta_{0} \frac{1}{p^{n}}+\beta_{1} \frac{1}{p^{n-1}}+\cdots+\beta_{n-1} \frac{1}{p^{1}}\right) p^{n}+\left(\beta_{n+1} p^{1}+\beta_{n+2} p^{2}+\cdots\right) p^{n} \tag{14}
\end{equation*}
$$

Then the unequal formula (11) is satisfied because right side $p^{n}$ is not retained its $n$.

Therefore, in order (8) is satisfied, every both side coefficients for same power of 3 terms should be equal. Then this makes following equations.

$$
\begin{align*}
& \left(2^{m}-3\right) n=1  \tag{15}\\
& \left(2^{m}-3\right) n \cdot 2^{m}=2^{m_{1}} \\
& \quad \cdots \cdots \cdots \cdots \cdots \cdots \\
& \left(2^{m}-3\right) n \cdot 2^{m(i-1)}=2^{m_{1}+m_{2}+\cdots+m_{i-1}}
\end{align*}
$$

$n$ is positive odd integer. m should be positive integer comparing both sides. Therefore, on (15),

$$
m=2, n=1
$$

Resolving all equations sequentially, we can get result (16).

$$
\begin{equation*}
m_{1}=m_{2}=\cdots=m_{i}=m=2 \tag{16}
\end{equation*}
$$

This means that this looping is only one member looping or self-looping when $\mathrm{n}=1$.
Therefore, $\mathrm{n}=1$ can be terminal point of Collatz Conjecture operation.

## 3. Consideration

No looping proof in this report could be used with *1 and *2 which investigate Collatz Conjecture Space. These show that the space expectation value of $2^{m_{i}}$ in (4) is $2^{2}=4$.
Also, no looping report could be used with *3 which investigates the series of Collatz Conjecture integer.

Therefore, these combinations show Collatz Conjecture is correct.
