# The Neutron Enigma II 

By Norbert Buchholz

#### Abstract

We had already dealt with the neutron enigma in an earlier paper ${ }^{5}$ and calculated values that were in excellent agreement with the decay times determined experimentally for the two measurement methods solely on the basis of the underlying masses or mass differences. However, this approach was formal, as no knowledge of the decay mechanisms was available and consequently the individual calculation steps could not be justified.

The solution approach presented here was based on the neutron decay mechanism described in a recent publication ${ }^{1}$ for calculating the decay curve. In combination with the specific structure of the two competing measurement methods, it was possible to predict that, in contrast to the bottle method, energy is continuously extracted from the system in the beam method, which leads to an increase in the lifetime of the neutrons, since energy and decay time are indirectly proportional, as already explained in the paper ${ }^{5}$ cited at the beginning.
The energy loss during the beam experiment could be quantified on the basis of a simple calculation model. From the resulting residual energy, it was possible to calculate the decay time, which corresponds to that measured by Greene3 within the standard deviation.

From the knowledge of the overall mechanism outlined above, some experimental modifications for the beam method can be proposed, which should lead to an approximation of the decay times for both methods:

- A reduction in diameter for the beam tube
- An increase in the suction voltage to remove the proton
- A reduction in the particle density in the beam tube

If these experimental changes lead in the direction we predicted, we can consider the neutron enigma solved.

## A Introduction

The confusing fact that different results far beyond the standard deviation were obtained when determining the decay time of the neutron using two different measurement methods, the bottle method and the beam method, appeared in popular science publications (see e.g. Ref 4) as the neutron enigma. For a more detailed description of the two methods, please refer to Ref 4 and 5.

In an earlier paper (Ref 5) we had calculated the decay times essentially from the rest mass of the proton divided by the rest mass difference of neutron and proton.

Bottle method
$T_{N 1}=\left(\frac{h}{\left(m_{N}-m_{P}\right) c^{2}} t_{p i x}-1\right)\left(\frac{1}{\sqrt{1-\left(\frac{1}{4}\right)^{2}}}\right)^{6}=879,24[s]$
Beam method
$T_{N 2}=\left(\frac{h}{\left(m_{N}-m_{P}-\frac{m_{e}}{\sqrt{k_{P_{e}}}}\right) c^{2}} t_{p i x}-1\right)\left(\frac{1}{\sqrt{1-\left(\frac{1}{4}\right)^{2}}}\right)^{6}=887,43[s]$

2Bottle method: TN1 $=878.5 \pm 0.8 \mathrm{~s}$
3Beam method: TN2 $=887.7 \pm 2.2 \mathrm{~s}$
This model was not based on any knowledge of the internal processes involved in the decay of the neutron. Thus, although the mass loss of $m_{e} / k_{\mathrm{pe}}{ }^{1 / 2}$ assumed quite arbitrarily in the second equation leads to an excellent result for the beam method, it could not be derived from any model. Nor were we able to justify the occurrence of the dimension factor $f_{D 4}$ to the 6th power.
What was ultimately impressive about these calculations was the excellent agreement with the measured values of Greene ${ }^{3}$ and Serebrov ${ }^{2}$.

## B Calculation of the potential energy in the beam experiment

In this paper we want to tackle the neutron enigma once again on the basis of our newly gained knowledge of the internal structure of the neutron.(Ref 1) The decisive difference between the bottle and beam methods is that in the bottle experiment the decay products are in a thermodynamic equilibrium until the particles are counted, whereas in the beam method the decay products electron and proton are continuously removed from equilibrium, with the proton being extracted and counted at the outer wall of the beam tube, which is connected as a cathode (see Fig. 1)

Fig. 1 (Ref. 4)
This has energetic consequences from the perspective of the oscillation model we developed in Ref. 1. According to this model, the decay of the neutron is based on the jumps of the electron from the potential space to the outer surface of the neutron. Due to the changing energy and mass at constant elementary particle density, the jump produces a periodic change in size, which is represented as a harmonic oscillation of the neutron surface. The electron is ejected from the neutron by the outwardly
directed counter-amplitude. Since the oscillation energy is a directed energy of the same magnitude in all spatial directions, only $1 / 6$ of the total energy is transferred to the object in the case of a targeted acceleration in one spatial direction.

The decay reaction is summarized as follows according to our model:
। $\mathrm{N}^{6 / 6} \rightarrow \uparrow^{\mathrm{P} 5 / 6}+\mathrm{e}^{1 / 6}$
A neutron with the full vibrational energy (6/6) releases $1 / 6$ of this as kinetic energy to the electron. If the resulting protons are only removed from the equilibrium in the above-mentioned form, there are no differences to the bottle experiment. The fact is, however, that energy can be transferred from another $\mathrm{N}^{6 / 6}$ to this proton by impact contact before it is removed from equilibrium

II $\mathrm{N}^{6 / 6}+\mathrm{P}^{5 / 6} \rightarrow \mathrm{~N}^{5 / 6}+\uparrow \mathrm{P}^{6 / 6}\left(\mathrm{f}_{\mathrm{u} 1}=1 ; 0.98 ; 0.96 \ldots . . . . .0\right)$
This process continuously removes energy from the system of neutrons. However, as we were able to show in our earlier work (Ref 5), lower energy in the system means a lower decay rate, i.e. a longer mean decay time, which would explain exactly why the decay times in the beam experiment are significantly higher than in the bottle experiment.

In the following, we want to quantify this time change by means of a simple thought experiment. We assume 100 neutrons that decay continuously, whereby one $\mathrm{N}^{6 / 6}$ is removed from the original system by the decay and another by the energy transfer according to reaction equation II. We are therefore dealing with a two-stage process per cycle. However, the equilibrium of reaction equation II is only initially on the far right-hand side. As the decay time increases, the composition of the reaction mixture and thus the reaction efficiency changes in the direction shown by the reaction arrow above. It is therefore necessary to introduce an efficiency factor ( $f_{u x}$ ), which very simply goes from 1 at the beginning to 0 at the end of the process. Since the decay process we postulate is a two-stage process, we have to count the factor in steps of two (see equation II or III in brackets).
In addition, we must take into account a back reaction according to equation III, whose factor is of course a mirror image (fu2 = 1-fu1).

III $N^{5 / 6}+P^{6 / 6} \rightarrow N^{6 / 6}+P^{5 / 6} \quad\left(f_{u 2}=0 ; 0.02 ; 0.06 \ldots . . . . .1\right)$
There are now two ways to combine the two reactions II and III. Either leave the reaction equations as shown above and multiply the factors $f_{u 1}$ and $f_{u 2}$ (see orange curve in Fig. 14 a). Or you mirror equation III and thus also the factor $f_{u 2}$, which then becomes $f_{u 1}$, and obtain $f_{u 1}{ }^{2}$ as the total factor (see orange curve in Fig. 14 b ). Although the course of the corresponding curves is very different, the calculations lead to exactly the same result in all cases, i.e. they are just different representations of the same process.

Fig. 14 a

Fig. 14
${ }^{2}$ Bottle method: TN1 $=878.5 \pm 0.8 \mathrm{~s}$
${ }^{3}$ Beam method: TN2 $=887.7 \pm 2.2 \mathrm{~s}$

The conversion of energy into time is carried out below, but the time results are already shown in the diagrams above, so they will be discussed briefly here.

The calculations with equally weighted consideration of the back-and-forth reaction ( $f_{u 1} \times f_{u 2}$ or $f_{u 1}{ }^{2}$ ) lead to a value of 888.8 s , which is only 1.1 s above the result given by Greene et al. (Ref 3) for the beam experiment and thus within the error limit of $\pm 2.2 \mathrm{~s}$ given there.
To check our calculation, we also tested how the decay time shifts if we include the back reaction (see Eq. III above) too strongly ( $f_{u 1} \times f_{u 2}{ }^{2}$ or $f_{u 1}{ }^{3}$ ) or not at all ( $f_{u 1}$ ) in the calculation. When overestimating the back reaction, we obtain a value of 884.5 s , as expected, which lies between the results of the bottle and beam experiment, and when ignoring the back reaction, we also obtain a value of 897.8 s , as expected, which is still approx. 10 s above that of the beam experiment, i.e. these calculations always tend to provide the correct results.

Table 3 shows the entire calculation for the resulting energy term using $f_{u 1}{ }^{2}$ as an example.
The sum of all energy contributions of the $\mathrm{N}^{6 / 6}$ (column V ) and the $\mathrm{N}^{5 / 6}$ (column VI ) is divided by the sum of all neutrons included in this calculation, i.e. by the sum of all contributions from columns III and IV. This gives the average potential energy for a neutron after a complete decay process.

## C The conversion of energy into time

The conversion of energy into time is also carried out over a length using the equation shown in the legend under D below. However, the energies calculated above must be subjected to a correction before they can be included in the calculation of time.

F $\quad t_{D_{N}}=t_{p e r} n_{t_{\text {max }}}[s]$
*The length-time conversion factors $\mathrm{f}_{\text {time1,2 }}$ were discussed in detail in Ref 1, last chapter.

The two factors 2 and $f_{d 42}{ }^{2}$ are not unknown, as they already played a role in the calculation of the natural constants $\alpha, \varepsilon_{0}$ and $\mu_{0}$ (see Ref. 7 ), but there always in the constellation $2 / f_{D 42}{ }^{2}$ or $f_{D 42}{ }^{2} / 2$. A more detailed explanation for the occurrence of these factors in this case in multiplicative form cannot yet be given at this point.
The further calculations of columns E and F are discussed in detail in the last section.
The decay times from the calculations in Table 4 have already been discussed above using the curves. Here we will only briefly discuss the value that is actually to be expected, which results from the difference in mass or energy between the neutron on the one side and the proton plus electron on the other ( 782.33 keV ). The calculated value (see Table 4, black line) of 877.95 is only 0.6 s below the value measured by Serebrov ${ }^{2}$ and thus within the specified standard deviation of 0.8 s .

Conclusion: The bottle experiment reflects the actual decay time of the neutron very accurately.
The detailed explanation given above for the different measured values in the measurement methods mentioned also makes it clear why the standard deviation in the beam experiments is significantly larger than in the bottle experiment, as the former measurement method uses an system of imbalance that reacts very sensitively to the exact performance of the experiment.
We can go even further and specifically change the experimental procedure in the beam experiment so that, ideally, the measurement results of both methods match.

For this purpose, the secondary reaction in $\beta$-decay must be eliminated as far as possible in accordance with reaction equation II, i.e. contact of the proton generated by the decay with an initial neutron before reaching the cathode must be prevented. This leads to the physical requirements mentioned below, which can be largely realized by the experimental changes shown on the right.

| Physical requirement (proton) | Experimental change |
| :--- | :--- |
| short transit path | Reduction of the tube diameter |
| short runtime | Increase in suction voltage |
| large free path | Reduction in particle density |

It would of course be of great interest to us if the beam experiments were carried out under the conditions, we have specified in order to verify or falsify our hypothesis presented here.

## D Quantization and dequantization

The last step in calculating the decay time of the neutron by means of the time quantum number $n_{\text {tmax }}$, i.e. the conversion of the period time $t_{\text {per }}$ with a duration of approx. $10^{-21} \mathrm{~s}$ into time periods corresponding to the macroscopically determined decay times (Table 4 column F), must also be explained in more detail.

As repeatedly pointed out in earlier works, minimal sizes are indispensable in a projection. Time and length and their combinations are of course the decisive variables in our system.

$$
\begin{aligned}
& t_{\min }=4,4077488 \cdot 10^{-24}[\mathrm{~s}] \\
& s_{\min }=1,3214098 \cdot 10^{-15}[\mathrm{~m}]
\end{aligned}
$$

Consequently, each quantity is "granular" and can only be represented in multiples of the minimum quantities (quantization).
$\mathrm{t}_{\mathrm{i}}=\mathrm{n}_{\mathrm{i}} \mathrm{t}_{\text {min }}$
$\mathrm{s}_{\mathrm{i}}=\mathrm{n}_{\mathrm{i}} \mathrm{s}$ min
Of particular importance are the maximum $n_{i}$ per unit size, which we will refer to below as the time or length quantum number.
These correspond approximately to the pixel numbers in electronic photography, which are known to indicate the number of the smallest, no longer resolved areas (pixels) per sensor chip and thus reflect its resolution and quality.

$$
\begin{array}{ll}
n_{t_{\max }}=\frac{t_{E}}{t_{\min }}=2,26873 \cdot 10^{23} & t_{E}=1 \mathrm{~s} \\
n_{s_{\max }}=\frac{s_{E}}{s_{\min }}=7,567674 \cdot 10^{14} & s_{E}=1 \mathrm{~m}
\end{array}
$$

In addition to the time and length quantum numbers, we have become familiar with the combination of these two as an important quantization variable when calculating the gravitational constant (Ref7).

$$
\begin{aligned}
& n_{g_{\max }}=\frac{s_{E} t_{E}}{s_{\min } t_{\min }}=1,716903 \cdot 10^{38} \\
& G=\frac{V_{P}}{6 m_{P} t_{\min }{ }^{2} n_{g_{\max }}} f_{D 4}=6,67377 \cdot 10^{-11}\left[\frac{\mathrm{~m}^{3}}{\mathrm{kgs}^{2}}\right]
\end{aligned}
$$

In order to make the calculation step described above for the calculation of the decay times (see Table 4, column F) plausible, we refer back to the calculation of the electric field constants in Ref 7.
We had solved the electrostatic force equation according to $\varepsilon_{0}$ and replaced the respective lengths and times with the corresponding minimum values as the decisive step.
${ }^{*} \varepsilon_{0}=\frac{e^{2} t^{2}}{4 \pi s^{3} m_{e}} \Rightarrow \varepsilon_{0}=\frac{e^{2} t_{\min }{ }^{2}}{4 \pi s_{\min }{ }^{3} m_{e}}=\frac{e^{2}\left(\frac{t_{E}}{n_{t_{\max }}}\right)^{2}}{4 \pi\left(\frac{s_{E}}{n_{s_{\max }}}\right)^{3} m_{e}}$
*In these equations, the factor $\mathrm{f}_{\mathrm{D} 42}{ }^{2} / 2$, which leads to the correct result but is uninteresting in this context, was not taken into account

We also achieve this substitution if we extend the numerator and denominator by the respective unit values and divide each of them by the corresponding quantum numbers (see equation system above
right). The result is identical, but it becomes much clearer that we have quantized the definition equation for $\varepsilon_{0}$ here.

By multiplying by the length or time quantum number, we can of course reverse the process. We therefore carry out a dequantization.

This is precisely the last step in calculating the decay times from the periodic times in Table 4 F.
$t_{D_{N}}=t_{p e r} n_{t_{\text {max }}}[s]$
We must therefore get used to the idea of a lack of quantization of time inside the neutron, which is another surprise when dealing with its inner life. Of course, everyone is free to consider this last step nonsensical and to regard the excellent agreement between the measured and calculated decay times of the neutron as pure coincidence. However, we are convinced that these values are very real and that the quantization of time is suspended inside the neutron. However, this also means that time has an infinite resolution in this area. The fact that the jumps nevertheless occur in the minimum time $t_{\text {min }}$, as postulated at the beginning, is obviously related to the fact that the oscillations induced by this have an external effect on our projection of time and space, which in turn makes quantization indispensable.
