Abstract. The stability of nickel nucleus $^{68}_{28}Ni$ compared to the $^{60}_{28}Ni$ and the instability of light nuclei with many neutrons are interpreted. Also, the elongation of heavy nuclei and the mechanism that acts as a catalyst for the nuclear fission of uranium $^{235}_{92}U$ are interpreted.

Keywords: Neutrons synod; beta decay $\beta^-$; nuclear fission.

PACS numbers: 03.50.Kk, 12.10.-g

1. General Appearance

According to the unified theory\textsuperscript{1,2} of dynamic space the atomic nuclei\textsuperscript{3,4} have been structured through two fundamental phenomena.\textsuperscript{5} The inverse electric field\textsuperscript{6} of the proton and the electric entity of the macroscopically neutral neutron.\textsuperscript{7}

The structure of the nuclei begins with the so-called lower-order nuclei, as the deuterium $^1_1H$, tritium $^3_1H$ and helium $^3_2He$, which evolve into helium $^4_2He^5$ and then the first upper-order oxygen\textsuperscript{8} $^8_{16}O$, that has four nuclei $^4_2He$ in a potential column of strong negative electric field as a follow:

Nitrogen nucleus$^9$ $^{14}_{7}N$ is derived from one carbon$^{10}$

$$^{12}_{6}C = 3^4_2He$$ \hspace{1cm} (1)

with addition of one deuterium $^2_1H$ and so

$$^{14}_{7}N = ^{12}_{6}C + ^2_1H = 3^4_2He + ^2_1H \Rightarrow ^{14}_{7}N = 3^4_2He + ^2_1H.$$ \hspace{1cm} (2)

Hence, oxygen nucleus$^8$ $^8_{16}O$ is derived from $^{14}_{7}N$ (Eq. 2) by completing of the deuterium $^1_1H$ as a helium $^4_2He$ and so (Fig. 1)

$$^8_{16}O = 3^4_2He + ^4_2He \Rightarrow ^8_{16}O = 4^4_2He.$$ \hspace{1cm} (3)
Interpretation of some nuclear phenomena

After the helium nucleus $2_8^4 H_e$, the oxygen nucleus $16_8^8 O$ is the second stable one in Nature and the first upper-order nucleus.

So, the second upper-order calcium nucleus $^{40}_{20} Ca$ (Fig. 2) is based on the fundamental natural phenomenon of mirror symmetry, by repetition of the first upper-order oxygen nucleus and one half of it, i.e. at the 2.5 factor
\[
^{40}_{20} Ca = 16_8^8 O + \frac{1}{2} \cdot 16_8^8 O + 16_8^8 O.
\] (4)

The same stands with the third upper-order tin nucleus $^{120}_{50} Sn$ (Figs 3, 4), which emerged from the second upper-order calcium $^{40}_{20} Ca$, according to the mirror symmetry and the same 2.5 factor plus 20 orbital bonding neutrons, i.e.
\[
^{120}_{50} Sn = 40_{20} Ca + \frac{1}{2} \cdot 40_{20} Ca + 40_{20} Ca + 20n.
\] (5)
Figure 3. Stereoscopic representation of the tin nucleus $^{120}_{50}Sn$, where the same image on the other three sides of the rectangular parallelepiped is repeated, while the lonely helium nucleus $^4_2H_e$ is placed in its center.

Figure 4. Top view of Fig. 3, where the mirror symmetry of the 2.5 factor for the construction of the tin nucleus $^{120}_{50}Sn$ appears.

Additionally, the tin $^{120}_{50}Sn$ will further form the basis for the structure of all heavy nuclei up to the radioactive uranium$^{14}_{92}^{235}U$ (Fig. 11).

Specifically, rhenium nucleus$^{15}_{75}^{187}Re$

$$^{187}_{75}Re = ^{120}_{50}Sn + \frac{1}{2} \cdot ^{120}_{50}Sn + 6n + n$$  \hspace{1cm} (6)
Interpretation of some nuclear phenomena

is constructed by one tin $^{120}_{50}Sn$, one half of it and six orbital bonding neutrons are added, while one neutron added in deuterium $^2H$ (one half helium $^4He$ located in the center of tin $^{120}_{50}Sn$, Fig. 4) that evolves into tritium $^3H$ (located in the center of $^{120}_{50}Sn$, indicatively see Fig. 5).

So, bismuth nucleus $^{209}_{83}Bi$ (Fig. 5)

$$^{209}_{83}Bi = ^{187}_{75}Re + 4^4He + 6n$$  \hspace{1cm} (7)

is constructed from the addition of four nuclei $^4He$ and six orbital bonding neutrons adjacent to the corner potential column of rhenium $^{187}_{75}Re$ (Eq. 6).

![Figure 5. Representation of the bismuth nucleus $^{209}_{83}Bi$, where appears the addition of four helium nuclei $^4He$ and six bonding neutrons adjacent to the corner potential column of rhenium nucleus $^{187}_{75}Re$.](image)

That is the simple and elegant structure model, according to which the nuclei consist of fixed nuclei $^4He$ (plus deuterium $^2H$, tritium $^3H$ and helium $^4He$, all evolving into helium $^4He$) and neutrons rotating around of them.

1.1. The stability of nickel nucleus $^{68}_{28}Ni$

The unexplained stability of the $^{68}_{28}Ni$ compared to $^{60}_{28}Ni$ is interpreted as follows:

Nickel nucleus $^{60}_{28}Ni_i$ (Fig. 6)

$$^{60}_{28}Ni_i = 2n + 2^4He + 40_{20}Ca + 2^4He + 2n$$  \hspace{1cm} (8)

is derived by addition of two helium nuclei $^4He$ right and left adjacent to a calcium nucleus $^{40}_{20}Ca$ (Fig. 2) as of two potential columns, while two orbital bonding neutrons at the above two potential columns are added, which reduce the strong negativity of the protons field and contribute to the stability of the nucleus.

However, nickel nucleus $^{68}_{28}Ni_i$ (Fig. 7)

$$^{68}_{28}Ni_i = ^{60}_{28}Ni_i + 8n$$  \hspace{1cm} (9)

have been constructed by addition of 8 orbital bonding neutrons to a $^{60}_{28}Ni$. These neutrons have been linked at the calcium nucleus during the tin $^{120}_{50}Sn$ (Figs 3, 4)
structure process. Therefore, the greater stability of the $^{68}_{28}Ni$, compared to the $^{60}_{28}Ni$, is due to its additional 8 neutrons.

**Figure 6.** Structure model of nickel nucleus $^{60}_{28}Ni = ^{40}_{20}Ca + 4^4He + 4n$, by addition of two helium nuclei $^4He$ right and left adjacent to a calcium nucleus $^{40}_{20}Ca$ (Fig. 2) as of two potential columns, while four orbital bonding neutrons are added

**Figure 7.** Structure model of nickel nucleus $^{68}_{28}Ni = ^{60}_{28}Ni + 8n$, where the additional of 8 orbital bonding neutrons to a $^{60}_{28}Ni$ (Fig. 6). These neutrons have been linked at the calcium nucleus during the tin $^{120}_{50}Sn$ (Figs 3, 4) structure process

1.2. The instability of light nuclei with many neutrons

Oxygen nucleus $^{28}_{8}O$ (Fig. 8)

$$^{28}_{8}O = ^{16}_{8}O + 12n$$

(10)

is constructed from the addition of 12 orbital bonding neutrons, which are placed in orbits between the helium nuclei of the oxygen $^{16}_{8}O$ (Fig. 1). A beta decay $\beta^-$ occur next, due to the frequent neutrons synod, making the oxygen nucleus $^{28}_{8}O$ unstable.

Magnesium nucleus $^{18}_{12}Mg$ (Fig. 9)

$$^{24}_{12}Mg = ^{16}_{8}O + 2^4He$$

(11)

is derived by addition of two helium nuclei $^4He$ adjacent to an oxygen nucleus $^{16}_{8}O$.

However, magnesium nucleus $^{32}_{12}Mg$ (Fig. 10)

$$^{32}_{12}Mg = ^{24}_{12}Mg + 8n$$

(12)

is constructed from the addition of 8 orbital bonding neutrons, which are placed in orbits between the helium nuclei of the magnesium $^{24}_{12}Mg$ (Fig. 9). A beta decay $\beta^-$ occur next, due to the frequent neutrons synod, making the $^{32}_{12}Mg$ with the many neutrons (i.e. 8 neutrons) greater unstable compared to the $^{24}_{12}Mg$. 
Interpretation of some nuclear phenomena

Figure 8. Structure model of oxygen $^{28}_8\text{O} = ^{16}_8\text{O} + 12n$ by addition of 12 neutrons in orbits between the helium of the oxygen $^{16}_8\text{O}$ (Fig. 1)

Figure 9. Structure model of magnesium nucleus $^{24}_{12}\text{Mg} = ^{16}_8\text{O} + 2^4_2\text{He}$, with addition of two helium nuclei $^2_2\text{He}$ adjacent to an oxygen nucleus $^{16}_8\text{O}$

Figure 10. Structure model of magnesium nucleus $^{32}_{12}\text{Mg} = ^{24}_{12}\text{Mg} + 8n$ with addition of 8 neutrons in orbits between the helium of the magnesium $^{24}_{12}\text{Mg}$ (Fig. 9)
1.3. The elongation of heavy nuclei

Figure 11. Representation of the uranium nucleus $^{235}_{92}U$, where appears the addition of one helium nucleus $^4He$, one tritium and one orbital bonding neutron at the middle potential column of bismuth nucleus $^{209}_{83}Bi$ (Fig. 5), while the addition of two helium nuclei $^4He$, two tritium nuclei and four orbital bonding neutrons appears at the other corner potential column of bismuth $^{209}_{83}Bi$. Also, the number and the distribution of protons determine the electrical potential and its isodynamic line that has a pear-shaped shape.

Uranium nucleus $^{235}_{92}U$ (Fig. 11)

$$^{235}_{92}U = ^{209}_{83}Bi + (2^4He + ^3H + n) + (2^4He + 2^3H + 4n)$$

is constructed from the addition of one helium nucleus $^4He$, one tritium $^3H$ and one orbital bonding neutron adjacent to the middle potential column of bismuth nucleus $^{209}_{83}Bi$ (Fig. 5), while two helium nuclei $^4He$, two tritium nuclei $^3H$ and four orbital bonding neutrons are added at the other corner potential column of bismuth nucleus.

Figure 11 shows the number and the distribution of protons in the structure of the uranium nucleus $^{235}_{92}U$, which determine its electrical potential. In the first four rows of potential columns (tin $^{120}_{50}Sn$) there are 60 protons, in the last two rows (right) of potential columns there are 27 protons, while in the middle row of the connection unit ($\frac{1}{2} \cdot ^{120}_{50}Sn$) there are only 5 protons. This distribution of protons creates 2 potential hills with an intermediate potential neck. The isodynamic line of this electrical potential has a pear-shaped shape.

Therefore, uranium nucleus $^{235}_{92}U$ (Fig. 11) is structured from helium nuclei $^4He$ (plus the tritium nuclei $^3H$), while the weak link of uranium $^{235}_{92}U$ is the unstable nucleus of the tritium $^3H$, which is located at the center of the above intermediate potential neck. This critical point becomes an attraction pole of neutrons, i.e. of a thermal neutron and rarely of a fast one, which it is cleaved (beta decay $\beta^-$), incorporating the produced proton into the tritium nucleus $^3H$, turning it into helium nucleus $^4He$. So,
Interpretation of some nuclear phenomena

this mechanism acts as a catalyst for the nuclear fission of uranium $^{235}_{92}U$ with the most common products being barium nucleus $^{141}_{56}Ba$ and the krypton nucleus $^{82}_{36}Kr$ plus three neutrons as in nuclear reaction

$$n + ^{235}_{92}U \rightarrow ^{141}_{56}Ba + ^{82}_{36}Kr + 3n. \quad (14)$$
