Models that link and suggest data about elementary particles, dark matter, and the cosmos

Thomas J. Buckholtz
Ronin Institute for Independent Scholarship, Montclair, New Jersey 07043, USA

Abstract
We suggest progress regarding the following six physics opportunities. List all elementary particles. Describe dark matter. Explain ratios of dark matter to ordinary matter. Explain eras in the history of the universe. Link properties of objects. Interrelate physics models. We use models based on Diophantine equations.

Keywords: Beyond the Standard Model, Dark matter, Galaxy formation, Neutrino masses, Evolution of the universe

1. Introduction

This unit previews physics results we propose, previews methods we use, and relates our work to other work in elementary particles, astrophysics, and cosmology.

1.1. Overview - physics results

This essay pursues the following two challenges. Describe new elementary particles and dark matter. Use descriptions of elementary particles and dark matter to explain astrophysics data and cosmology data.

Our explanations regarding large-scale data might help validate our descriptions of possible new elementary particles and our description of dark matter.

1.2. Overview - research and results

Figure 1 diagrams how - from bases through results - regarding our research. Our work has roots in the known elementary particles and in concordance cosmology. Our work features a hypothesis that nature includes six isomers of known elementary particles - of which only one isomer associates with ordinary matter and five isomers associate with most dark matter. Our work features new modeling based on Diophantine equations. We suggest new elementary particles and a specification for dark matter. We suggest insight regarding modeling gravity and regarding galaxy formation. We suggest explanations for known data for which - seemingly - other modeling does not offer explanations. We suggest data - about aspects of the universe - that people might be able to verify or refute.

Figure 2 alludes to all known elementary particles and to elementary particles that our work suggests. (Perhaps, preview table 10)

Figure 3 shows quantitative ratios of dark matter effects to ordinary matter effects. (Perhaps, preview table 19) Our work suggests quantitative explanations for the ratios. The explanations have bases in our specification for dark matter. The specification has roots in our hypothesis that associates with six isomers of known elementary particles. Each isomer of known elementary particles associates - approximately - with its own photon. Each isomer of known elementary particles associates with its own 0.5M, 0.5R, 0I, and 1J elementary particles.

Figure 4 suggests details about our explanation for the known ratio - five-plus to one - of dark matter density of the universe to ordinary matter density of the universe. (Perhaps, preview table 20)

Figure 5 suggests eras in the evolution of the universe. (Perhaps, preview table 17) As far as we know, direct observations and data associate only with the two multi-billion-years eras.

Figure 6 suggests eras in the evolution of - and various ratios of dark matter to ordinary matter for - galaxies. (Perhaps, preview table 19 and table 20) People have observed galaxies that associate with each one of the suggested approximate ratios - one to zero-plus, five-plus to one, four to one, and zero-plus to one.

Figure 7 suggests possible relationships between physics properties. (Perhaps, preview table 11 and table 13) This essay leaves open possible opportunities to use these possible relationships to envision possibilities more - than this essay explores - fundamental aspects of nature.

Figure 8 suggests possible rest energies for all known elementary fermions (including neutrinos) and all suggested elementary fermions. (Perhaps, preview table 12, table 13, and table 14) This essay associates each rest energy with direct use of or extrapolation from a few formulas. (Perhaps, preview table 13 and table 14)

1.3. Overview - methods

One goal of our modeling is to match and possibly extend a list of properties - of objects - that people infer or might infer based on observations based on so-called long-range interactions (or, so-called long-range forces). Long-range interactions include electromagnetism (which associates with notions of a spin-one boson - the photon), gravity (which associates with notions of a yet-to-be-found spin-two boson - the graviton), possibly interactions that would associate with a spin-three boson, and possibly interactions that would associate with a spin-four boson.

We find it convenient to divide elementary particles into three sets - carriers of long-range interactions, other elementary bosons, and elementary fermions. We associate, respectively with the three sets, the symbols LRI (as in long-range interaction or as in elementary boson that associates with a long-range interaction), SRI (as in short-range interaction or as in elementary boson that does not associate with a long-range interaction), and ELF (as in elementary fermion).

We associate the word simple - as in the phrase simple elementary particle - with the SRI elementary bosons and the ELF elementary fermions, but not with the LRI elementary bosons.

We develop mathematics modeling that outputs characteristics of long-range interactions and properties - of objects - that long-range interactions measure. The modeling features solving Diophantine equations.

LRI solutions come in pairs. For example, regarding electromagnetism, one so-called PROP solution associates with the property of charge. That PROP solution has a so-called CURR partner solution that associates with a current of charge. We
Figure 1: Research flow - from roots to results.

Figure 2: Known and suggested elementary particles. The following sentences introduce symbols for and notions about suggested new elementary particles. (The number $S$ in a symbol $S\Phi$ associates with elementary-particle spin in units of $h$. $0.5X$ associates with three spin-one-half heavy neutrinos. $2G$ associates with a spin-two graviton. $0I$ and $1J$ associate with a spin-zero zero-charge analog to quarks. $0.5R$ associates with three spin-one-half zero-charge analogs to quarks. $1W$, $1Z$, and $1U(8)$ associate with a spin-one heavy boson. $2G$ associates with a spin-two graviton. $4G$ associates with a spin-four relativistic particle that associates with Pauli repulsion.)

Legend:
- $S$ - spin in units of $\hbar$ ($S$ as in $S(S+1)/2$)
- $m$ - mass, $m=0$ denotes zero.
- $\Phi^{0}$ - charge of the form $\Phi^{0} = (\text{Number of particles})$ (if more than one particle).
- $0H$ - Higgs boson
- $0.5C_{(3)}$ - three charged leptons
- $0.5N(3)$ - three neutrinos
- $0.5M(3)$ - three heavy neutrinos
- $1W$, $1Z$ - $W$ boson, $Z$ boson
- $0.5R(3)$ - three analogs to quarks
- $0.5Q_{(2/3)}$, $0.5Q_{(1/3)}$ - six quarks
- $0I$ - $I$ boson (inflaton)
- $1J$ - $J$ boson (Pauli repulsion)
- $1U(8)$ - eight gluons

Free - can model as free. Entwined - models as entwined. (Complicated) - some $G$ components associate with Free and some $G$ components associate with Entwined.
### Ratios of dark matter effects to ordinary matter effects

Legend:
- DM - dark matter
- OM - ordinary matter
- DM:OM - ratio of dark matter effects to ordinary matter effects

Figure 3: Ratios of dark matter effects to ordinary matter effects. For each ratio except two of the ratios, the following three sentences pertain. People have observed the ratio. People attribute the so-called dark matter effects to dark matter. Our modeling explains the ratio. Regarding some specific depletion of cosmic microwave background radiation (or, CMB), people have observed the ratio, some people speculate that the effects that people might not attribute to ordinary matter are effects of dark matter, and our modeling suggests that non-ordinary-matter effects are effects of dark matter. We use the two-word term early galaxies to include galaxies observed at redshifts of at least (and possibly somewhat less than) seven. Most relevant data about later galaxies pertains to galaxies observed at redshifts considerably less than seven. The three-word term dark matter galaxy pertains to a galaxy for which the DM:OM ratio is one to zero-plus. Possibly, current techniques are not adequately sensitive to detect early dark matter galaxies.

### Dark matter and ordinary matter

(Relative densities of the universe – dark matter : ordinary matter :: 5+:1)

Legend:
- Isomer – an isomer of all elementary particles except IG elementary particles (or, except [mainly] the photon and the graviton).
- DM – dark matter
- OM – ordinary matter
- DMAI – dark matter : ordinary matter
- IGM – intergalactic medium
- OMSE – ordinary-matter similar elementary particles and includes all elementary particles except IG particles, 0.5R, and 0.5N.

Each of 0.06 and 1.00 is a relative density of the universe. The total relative densities are ~5.38 DM and 1.09 OM.

Figure 4: Dark matter density of the universe and ordinary matter density of the universe. The DM (or, dark matter) relative densities sum to approximately 5.38 times the OM (or, ordinary matter) relative density. Across isomers, the masses of similar elementary particles are identical. However, for charged leptons, associations between flavour and mass are not necessarily identical. Differences in associations between charged-lepton flavour and charged-lepton mass lead to differences in the evolution of stuff that associates with each isomer. The stuff that associates with at least four DM isomers of elementary particles evolves so that the associated IGM (or, intergalactic medium) does not interact electromagnetically much with itself, compared to the interactivity of OM IGM. The lack - across at least four DM isomers - of much IGM electromagnetic self-interaction might associate with observations regarding the Bullet Cluster collision of two galaxy clusters.
Figure 5: Suggested and known eras regarding the rate of expansion of the universe. The era that associates with a row in the table precedes eras that associate with subsequent rows in the table. For each row, the leftmost three columns describe aspects of the era. The rightmost four columns associate with a noteworthy cause for the era. Generally, the noteworthy cause gains prominence before the era starts. Our work proposes the first two eras to which the image alludes. Other work and our work suggest the era of inflation. Other work and our work model aspects of the two multi-billion-years eras. Our work might explain seeming difficulties that other work seems to exhibit regarding modeling aspects of the current multi-billion-years era of increasing rate of separation.

</tbody>
</table>

Legend:
The stage that associates with a row in the table precedes stages that associate with subsequent rows in the table.
Initiating forces might tend to gain prominence before - and dominate for at least early parts of - the respective stages.
RDF - radial dependence of force ($r$ denotes the distance between two significantly massive objects.).
Reach (for one instance of the initiating force) - number of isomers.
Some galaxies do not evolve beyond the first era. Some of these galaxies have essentially only ordinary matter. Some have essentially only dark matter.
During the second stage, the repulsive force component also repels some stuff that associates with the isomer that associates with the original clump.
Based on the repulsive force, some galaxies have nearby stuff that associates essentially with only five isomers.
Some galaxies do not evolve beyond the second era. A DM:OM ratio of 5:1 can persist. [DM - dark matter; OM - ordinary matter]
Collisions can merge stuff from galaxies for which the original-clump isomers differ.
Some galaxies might associate with more than one original clump and with more than one original-clump isomer.

Figure 6: Suggested eras and suggested DM:OM ratios for galaxies. The stage that associates with a row in the table precedes stages that associate with subsequent rows in the table. For each row, the leftmost two columns associate with aspects of the stage. The rightmost four columns associate with a noteworthy cause for the stage. The noteworthy cause might gain prominence before the stage starts. Some galaxies do not transit beyond some stages. Our work points to possible propensities for nature to form galaxies with DM:OM ratios of approximately one to zero-plus (that is, dark matter galaxies), five-plus to one, four to one, and zero-plus to one. Galaxies that both had more than one original clump and had three original-clump isomers might tend to cease star formation earlier than do some other galaxies.
Possible relationships between physics properties

(Based on properties of some elementary particles)

Possible relationship – for elementary bosons – between the properties of mass, spin, and charge

\[(\text{Mass})^2 = (\text{Mass}_{\text{Higgs}})^2/17 \times (j^2 + L^2 - S^2 - Q(Q+1))\]

Possible relationship between electromagnetism and gravity (interrelates one charge and two masses)

Define \(\beta'\): \(\beta' \equiv m_{\text{tau}}/m_e\)

\(\beta' = \beta\)

Legend:

- \(j\) for the Higgs boson (8), 3 for the Z boson (12), 3 for the W boson (18), and 5 for all other elementary bosons.
- \(S\) for spin (in units of \(\hbar\)).
- \(L_{\mu} = 1\) for the Higgs boson (8), 1 for the Z boson (12), 1 for the W boson (18), and 0 for all other elementary bosons.
- \(Q = \text{charge} / (\text{charge of the electron})\).

\((\text{Mass}_{\text{Higgs}})^2 / (4\pi\alpha)\) is the ratio – for two electrons – of electromagnetic repulsion to gravitational attraction.

\((\beta')^2\) is the ratio of the gravitational attraction between two taus to the gravitational attraction between two similarly (to the two taus) distant electrons.

The exponent of 6 – in the definition for \(\beta\) – might associate (for some modeling) with the notion of 6 isomers of non-G-family elementary particles.

Figure 7: Possible relationships between physics properties. The boson-centric relationship might pertain for all known elementary bosons and for all new bosons that we suggest. The possible relationship between electromagnetism and gravity enables computing a tau mass that is compatible with experimental results.

Exp = Result from experiments.
Calc = Result from a calculation. The standard deviation reflects the standard deviation of measurements of \(G_P\).

Figure 8: Possible rest energies for elementary fermions. Eight standard deviations of the calculated tau rest energy fit within one standard deviation of the measured tau rest energy. The calculated quark masses comport with experimental results. Results regarding neutrinos comport with the notion of three (not heavy) neutrinos and with astrophysics data. Our work suggests possible ranges for the masses of each of the three possible arc elementary fermions. Our work suggests a possible lower limit for the masses of the three possible heavy neutrino elementary fermions.
think that each LRI pair of one PROP solution and its CURR partner can adequately associate with special relativity and can adequately associate with kinematics models that do not have bases in special relativity.

Our LRI modeling for electromagnetism has some similarities to modeling based on charge-and-current 4-vectors and has some parallels to modeling based on an electric field, a magnetic field, and Maxwell’s equations. However, some differences pertain. For example, LRI modeling includes a PROP solution that associates with a component of magnetic field that associates with the notion of charge dipoles. That PROP solution has a CURR partner that associates with a current of charge dipoles.

Our LRI modeling for gravitation has similarities and differences with respect to gravito electromagnetism. (Regarding gravito electromagnetism, see references [1] and [2].)

SRI solutions and ELF solutions come in PROP and CURR pairs. Each known simple particle associates with a solution pair. Each not-yet-found simple particle that this essay suggests associates with a solution pair.

We think that modeling based on the LRI, SRI, and ELF aspects discussed above suffices to point to possibly relevant new physics. For example, we interpret our modeling as describing aspects of two possible eras - in the evolution of the universe - before the possible inflationary epoch. And, we interpret our modeling as suggesting a mechanism that leads to the recent multi-billion-years era increases in the rate of expansion of the universe.

However, modeling just based on LRI, SRI, and ELF aspects discussed above does not suffice to explain some data about ratios of dark matter to ordinary matter and does not suffice to explain the magnitude of the recent multi-billion-years era increases in the rate of expansion of the universe. (Regarding ratios of dark matter to ordinary matter, perhaps preview table 20) Regarding the magnitude of the recent multi-billion-years era increases in the rate of expansion of the universe, perhaps preview the notion of reach - or \( \rho_1 \) - in table 17.

To explain some data about ratios of dark matter to ordinary matter, we posit that nature includes six isomers of the set of simple (or, SRI and ELF) elementary particles. Ordinary matter associates with all of the simple particles in so-called ELPI0. The symbol ELPI denotes the three-word phrase elementary particle isomer. The integers \( l \) that associate with symbols of the form ELPI range from zero to five. Dark matter associates with some yet-to-be-found ELF particles in EPLI0 and with all elementary particles in ELPI1 through ELPI5.

The symbol STUI denotes stuff - such as hadron-like particles, atoms, and stars - made up of just (or essentially just) ELPI\( l \) elementary particles (plus LRI aspects that include electromagnetism and gravity).

We posit that, across isomers, the ELPI have similarities. We posit that the mass of each simple particle in any one isomer is the same as the mass of a counterpart simple elementary particle in each other isomer.

We posit that the six ELPI differ in at least one way. For each of isomer-zero and isomer-three, the flavour of the lowest-mass charged lepton equals the flavour for the two lowest-mass quarks. For each of the other four isomers, the flavour of the lowest-mass charged lepton does not equal the flavour of the two lowest-mass quarks. (Perhaps, preview table 16) One possible other difference between isomers might be that ELPI0, ELPI2, and ELPI4 associate with left-handedness (for, at least, charged leptons) and ELPI1, ELPI3, and ELPI5 associate with right-handedness.

Regarding LRI, a so-called reach associates with each PROP-and-CURR pair. We use the symbol \( \rho_1 \) to denote reach. Allowed values for \( \rho_1 \) are one, two, and six. For relatively familiar physics - such as the physics of solar systems - the dominant gravitational PROP-and-CURR pair has a reach of six. The six STUI interact with each other via this component of gravity. Regarding electromagnetism, the reach that associates with the charge-and-charge-current PROP-and-CURR pair is one. The reach that associates with the charge-dipole-related-current PROP-and-CURR pair is one. Each one of the STUI has, in effect, its own instance of each of these two electromagnetic-centric PROP-and-CURR pairs. Each STUI does not interact with any other STUI via either of these two electromagnetic-centric PROP-and-CURR pairs.

The notion of six isomers and the notion of instances of LRI PROP-and-CURR pairs seem to suffice to explain ratios of dark matter to ordinary matter. (Perhaps, preview table 20) The two notions might suffice to explain the size of the recent multi-billion-years era increases in the rate of expansion of the universe.

1.4. Relationships between our work and other work

We discuss relationships between our work and other work. Here, other work includes observational research and modeling-centric research.

1.4.1. We discuss relationships - between our work and other work - regarding elementary particles, physics constants, and physics properties.

We discuss other work that tries to suggest new elementary particles.

Reference [3] lists some types of modeling that people have considered regarding trying to extend
the elementary particle Standard Model, including trying to suggest elementary particles that people have yet to find. Types of models associate with terms such as large extra dimensions, Kaluza-Klein (which associates with notions of gravity in more than four dimensions), grand unification, supersymmetry, and superstrings. Reference [4] provides information about some of these types of modeling. References [5], [6], and [7] provide some information about modeling and about experimental results. Reference [8] provides other information about modeling and about experimental results. (Perhaps, see reviews numbered 86, 87, 88, 89, 90, and 94.)

We discuss possible elementary particles that people have yet to find, that we suggest, and that other people might suggest.

Reference [4] suggests the notions of dark matter charges and dark matter photons. We suggest dark matter isomers of charged elementary particles and, in effect, dark matter components - such as components associating with electrostatics and magnetostatics - of electromagnetism.

Reference [10] suggests the notion of a so-called inflaton field. We suggest an inflaton elementary particle. (Perhaps, preview table 10 and note the Of boson.)

People suggest the notion of a graviton. (See, for example, reference [11].) We suggest a graviton. (Perhaps, preview table 10.)

Reference [12] discusses notions of sterile neutrinos and heavy neutrinos. We suggest possible elementary particles that might associate with notions of heavy neutrinos. (Perhaps, preview table 10)

We discuss possible elementary particles that people have yet to find, that we suggest, and for which other people might suggest that modeling rules out possible existence.

We suggest a spin-three analog to the photon and graviton. (Perhaps, preview table 6.) We suggest a spin-four analog to the photon and the graviton. (Perhaps, preview table 6) Some people suggest limits - that might preclude massless elementary particles that would have spins of more than two - that people might interpret QFT (or, quantum field theory) as implying. This essay de-emphasizes discussing such possible limits.

We discuss possible elementary particles that people have yet to find and our modeling seems not to suggest.

Reference [7] reviews modeling and experiments regarding so-called magnetic monopoles. Reference [7] notes that a symmetry regarding Maxwell’s equations suggests that nature might include magnetic monopoles. We suggest that nature might not include an interaction that would associate with magnetic monopoles. (Perhaps, preview table 3.)

Reference [9] reviews modeling and experiments regarding so-called magnetic monopoles. We suggest that nature might include magnetic monopoles. We suggest that nature might not include magnetic monopoles. (Perhaps, preview table 7.) We suggest an axion elementary particle. We suggest that nature might include axions. We suggest that nature might not include axions. (Perhaps, preview table 7.) We suggest that phenomena that people might attribute to axions might not associate with axions. One such phenomenon could be electromagnetic interactions between ordinary matter and dark matter based, for example, the so-called 1g1`2`4 component of electromagnetism. (Perhaps, preview table 3 and table 9.)

Reference [6] reviews modeling and experiments regarding so-called leptoquarks. We suggest that nature might not include leptoquarks. (Perhaps, preview table 7.)

We discuss neutrino masses and oscillations.

Reference [12] discusses modeling and data about neutrino masses and oscillations.

We suggest neutrino masses. (Perhaps, preview table 14.) We also suggest that, in effect, gravity measures neutrino masses and a spin-three analog (to electromagnetism and gravity) measures neutrino flavours. (Perhaps, preview table 14.) As far as we know, our modeling is not incompatible with data that reference [12] discusses. Future experimentation might help validate or refute aspects of our work regarding neutrinos.

We discuss gravitation.

We suggest effects - associating with isomers of elementary particles and with reaches of components of gravity - that suggest that other modeling regarding gravity would not be adequately accurate for some circumstances. This essay discusses some such circumstances. We are uncertain as to the extent to which aspects that reference [13] or reference [14] discuss would tend to validate or refute aspects of our modeling that pertains to gravitation.

We use modeling - regarding gravity - that has some similarities to models that people associate with the term gravitoelectromagnetism. (References [11] and [12] discuss gravitoelectromagnetism.) Our modeling regarding gravity has some similarities to models that use classical physics perturbations regarding Newtonian gravity. (Reference [14] deploys modeling that associates with non-spherical distributions of mass.)

We discuss physics constants and properties.

Our work seems to interrelate some physics constants. (Perhaps, preview table 11 and table 13.)

We might offer new approaches to estimating
some physics properties. This essay points to masses - that would comport with recent experimental results and that would have smaller standard deviations than standard deviations that associate with recent experiments - for each of the tau elementary fermion and the Higgs boson. (Perhaps, preview respectively table 13 and table 11.) This essay notes - regarding the anomalous magnetic dipole moment of the tau elementary fermion - a possible estimate that might approximate a Standard Model estimate. (Perhaps, preview discussion related to table 12 and table 13.) This essay notes - regarding the fraction of top quark decays that result in right-handed W bosons - a possible estimate that might approximate a Standard Model estimate.

1.4.2. We discuss relationships - between our work and other work - regarding cosmology.

We think that - with some exceptions - our work does not necessarily suggest significant changes - to concordance cosmology - regarding the large-scale evolution of the universe. (References [16], [17], and [18] review aspects of concordance cosmology.) Each exception associates either with a possible aspect of nature for which people have no observations or with a known gap between observations and concordance cosmology.

One exception pertains regarding before inflation. One exception pertains regarding recent changes in the rate of expansion of the universe. In each case, we suggest noteworthy contributions by a gravitational force component for which each instance (of the component) has a reach that is greater than one isomer. (Perhaps, preview table 9.) For times associating with between the two cases, we suggest dominance by gravitational force components that have reaches of one isomer. For times associating with between the two cases, we do not propose significant incompatibilities between our work and large-scale concordance cosmology.

We discuss a possibility regarding times before inflation. (Reference [17] discusses inflation.) We think that no direct observations pertain. We suggest two eras before inflation. (Perhaps, preview table 17) The first of those two eras features aspects that the Standard Model and concordance cosmology do not include. One aspect is the so-called jay boson. (Perhaps, preview table 10 and table 17) The other aspect is the so-called 2g1:2·3:8·16 component of gravity. (Perhaps, preview table 17) An instance of that component has a reach of six isomers. For purposes of discussion, we assume that the universe transited those two eras. We assume that concordance cosmology can embrace the jay boson. For the first of those two eras, an extrapolation of concordance cosmology techniques might underestimate the strength of the key driver - the 2g1:2·3:8·16 component of gravity - by a factor of six.

We discuss phenomena during and after the lead-up to the current multi-billion-years era of increases in the rate of expansion of the universe.

Various people suggest that concordance cosmology underestimates increases in the rate of expansion. (References [18], [19], [20], [21], and [22] discuss relevant notions.) We think that we point to a basis for the underestimates. Regarding times before that lead-up, we suggest dominance by an attractive quadrupole gravitational force component - 2g1:2·3. (Perhaps, preview table 17) Each instance of that force component has a reach of one isomer. Before and during the recent multi-billion-years era, the 2g2:4 gravitational force component gains prominence and then becomes dominant. Each instance of 2g2:4 has a reach of two isomers. We suggest that concordance cosmology models that work well regarding times for which reach-one dominance pertains would not necessarily work well after those times. We suggest that extrapolating based on such concordance cosmology modeling would underestimate (conceptually by a factor of two) the strength of the driver for increases in the rate of expansion. We suggest that - to get good results via concordance cosmology modeling - people might adjust the equation of state. In general, for each relevant density, components of pressure that associate with repulsion need to increase.

Our suggested resolution regarding the underestimate seems to differ considerably from possible resolutions based on concordance cosmology modeling. Our suggested resolution focuses on phenomena that would pertain at the times for which concordance cosmology modeling seems not to be adequate. Other possible resolutions seem to focus on phenomena early in the history of the universe. (See reference [18].)

1.4.3. We discuss relationships - between our work and other work - regarding astrophysics.

We think that our modeling is not necessarily incompatible with astrophysics data or with results based on concordance cosmology modeling. (Here, we assume that the two-word term concordance cosmology includes aspects that associate with dark matter, astrophysics, and effects of gravity on scales as small as one galaxy.)

We discuss properties of dark matter. Reference [23] suggests the following notions. Most dark matter comports with notions of cold dark matter. Models that associate with the two-word term modified gravity might pertain; but - to the extent that the models suggest long-range astrophysical effects - such models might prove problematic. People suggest limits on the masses of ba-
2. Methods

This unit develops and deploys modeling that matches all known elementary particles; suggests new elementary particles; interrelates elementary particles, properties of individual objects, and properties of systems of objects; and provides specifications for dark matter.

The method that we develop here outputs solutions to equations that involve sums of integers.

Some solutions associate with modeling that has similarities to modeling based on Maxwell’s equations, to modeling based on charge-and-current 4-vectors, or to modeling based on the notion of gravitoelectromagnetism. (References [11] and [2] discuss gravitoelectromagnetism.) Some solutions associate with electromagnetic fields - such as an electric field or a magnetic field - and with electromagnetic properties - such as charge and magnetic dipole moment - of systems. Some solutions associate with gravitational fields and with gravitational properties - such as mass.

Some solutions point to radial spatial dependences of potentials. (Regarding radial spatial dependences of potentials and forces, we use terminology that generally associates with Newtonian kinematics.) One such radial spatial dependence of potential is \( r^{-3} \) for a component of electromagnetism that associates with the charge of a system. Here, \( r \) denotes a distance away from the system that produces the component of electromagnetism. Another such radial spatial dependence of potential is \( r^{-2} \) for a component of electromagnetism that associates with the magnetic dipole moment of the system. (Generally, for radial spatial dependences other than \( r^{-1} \), angular dependences also pertain.)

We associate the symbol 1g with solutions that associate with electromagnetism. Here, the one denotes the spin (in units of \( \hbar \)) of photons. We associate the symbol 2g with solutions that associate with gravitation. Here, the two denotes the spin (in units of \( \hbar \)) of (as yet not detected) gravitons. We associate the symbol 3g with solutions that might associate with a would-be spin-three elementary boson. We associate the symbol 4g with solutions that might associate with a would-be spin-four elementary boson. We associate the two-element term long-range force (or, the two-element term long-range interaction) with each one of 1g through 4g.

Other solutions associate mathematically with 0g. Some 0g solutions associate with elementary bosons, such as the Z boson and the W boson. Some 0g solutions associate with elementary fermions, such as quarks and charged leptons.

The method outputs solutions that seem to match all known elementary particles and that suggest new elementary particles.

We use the following method to catalog elementary particles. (Perhaps, preview table 10.) A symbol of the form \( S \Phi \) associates with a so-called family of elementary particles. Each elementary particle associates with one family. Each family associates
with one of one, three, or eight elementary particles. For a family, the value $S$ denotes the spin (in units of $\hbar$) for each elementary particle in the family. $S$ associates with the expression $S(S+1)\hbar^2$ that associates with angular momentum. Values of $S$ include 0, 0.5, 1, and 2 and might include 3 and 4. The symbol $\Phi$ associates with a symbol of the form $X_Q$, in which $X$ is a capital letter and $Q$ is the magnitude of charge (in units of $|q_e|$, in which $q_e$ denotes the charge of an electron) for each particle in the family. For cases for which $Q = 0$, this essay omits - from the symbols for families - the symbol $Q$. (Perhaps, preview table 10)

2.1. Charge, mass, other properties, and elementary particles

This unit develops and deploys modeling that interrelates long-range forces (such as electromagnetism and gravity), properties of individual objects, properties of systems that include individual objects, and elementary particles.

2.1.1. We explore notions that point toward aspects of some modeling that our work uses.

We imagine two non-moving objects - object A and object B - that are located a distance $r$ from each other. Each object has non-zero charge and non-zero mass. We consider the impacts of fields - such as electromagnetism or gravity - generated by object A on object B.

The electric potential that affects object B varies as $r^{-1}$. The gravitational potential that affects object B varies as $r^{-1}$.

We imagine hypothetical effects that associate with hypothetical interactions by object B with a hypothetical combination - produced by object A - of electric field and gravitational field. We imagine that the potential that associates with these interactions varies as $r^{-1}$ times $r^{-1}$, which equals $r^{-2}$.

We discuss aspects of hypothetical particles that might intermediate interactions between object A and object B. We use the two-term object C to denote such a hypothetical particle. We imagine that objects C traverse straight-line trajectories from object A to object B. We use the word axis to associate with the straight line.

We imagine objects C that have some similarities to and some differences from either an atom or a solar system. One or more components of an object C orbit a point that is central to object C. An object C exhibits orbitals. We imagine that, with respect to the axis that runs from object A to object B, each orbital associates with a unique magnitude $l\hbar$ of orbital angular momentum. Here, $l_o$ is a positive integer. Up to one entity can associate with (or, occupy) an orbital. The integer $l_{\text{max}}$ denotes the maximum value of $l_o$ that associates with an occupied orbital. Relative to the axis that runs from object A to object B, the angular momentum that associates with an occupied orbital is one of $-l_o\hbar$ and $+l_o\hbar$. (We exclude - for the occupied orbital - that associates with $l_o$. Values of $l$ for which $-l_o < l < +l_o$.) The angular momentum that associates with an unoccupied orbital is $0\hbar$. (Regarding considering the object to be atom-like, the following notions pertain. The nucleus has zero spin. Entities that occupy orbitals have zero spin. Entities that occupy orbitals do not interact with each other.) Relative to the axis, the total angular momentum that associates with an object C is the sum - over the occupied orbitals - of the respective $\pm l_o\hbar$.

Regarding modeling that we discuss below, the following notions pertain.

- Individual objects C do not associate directly with elementary particles.
- Mathematical modeling regarding an object C associates with a so-called (mathematical) solution. Some sets of solutions associate with modeling for LRI (or, long-range interaction) elementary particles such as the photon. Some sets of solutions associate with modeling for SRI (or, short-range interaction) elementary bosons such as the W boson. Some sets of solutions associate with modeling for ELF (or, elementary fermion) elementary fermions such as the electron.
- Spatial dependences of potentials can depend on angular coordinates as well as on a radial coordinate such as $r$.
- We suggest that the modeling explains data (some of which other modeling seems not to explain), echoes useful modeling (that other people have developed), and predicts possibly reasonable data that might result from future observations and experiments. This essay does not necessarily point directly to a perhaps so-called fundamental basis for the modeling.

2.1.2. We develop a mathematical basis for modeling that this essay features.

We focus on mathematics that associates with the discussion about objects C and orbitals. We do not explore the notion of direct physics relevance for such objects. We do not explore the notion of such objects. For convenience, we continue to use the word orbital.

The discussion about hypothetical objects C suggests expressions of the form $\sum_{o \in O}(\pm l_o)$. Here, $O$ associates with the set of occupied orbitals. The integer $o$ denotes a member of $O$.

We use the symbol $\Gamma$ to denote an ascending-order list of the relevant $o \in O$. Within a list $\Gamma$, we separate values of $l_o$ by using the symbol `. The symbol $l_{\text{max}}$ denotes the maximum value of $l_o$ in $\Gamma$. 

11
right-circular polarization.

Table 2 discusses interpretations - regarding properties of an object - regarding $\Sigma g'$ solutions for which $1 \leq \Sigma \leq 2$ and $1 \leq l_{\max} \leq 4$.

Table 2 suggests two uses for the words monopole, dipole, quadrupole, and octupole. One use associates with mathematics and with table 1. One use associates with physics and with the dependence of potentials that associate with the modeling of components of LRI-centric interactions (or, LRI forces).

We posit that a solution associates with a so-called RDP of the form $\Xi^{-1}$, RDP stands for radial dependence of potential. Here, we consider Newtonian modeling for potentials (as in potential energy) that associate with fields (such as the electromagnetic field and the gravitational field) that an object produces. For a solution other than a monopole solution, the potential can (and generally does) vary based on angular coordinates (as well as based on a radial coordinate). We posit that $\Xi^{-1} = r^{-1}$, in which $r$ is the spatial distance from the object. (We provide a cautionary note regarding terminology. Per table 2, we associate the solution for which $\Sigma$ is one and $\Gamma$ is 1 2 4 with each one of the following: $\Xi^{-3}$ and hence mathematical quadrupole, $r^{-3}$ and hence a behavior of potential that associates with a notion of quadrupole, and a physics object that associates with a magnetic dipole that rotates around an axis that does not equal the axis that associates with the magnetic dipole. One way to think about the seeming tension between quadrupole and dipole is to associate the factor $\Xi^{-1}$ that associates with $l_0 = 4$ with $(ct)^{-1}$ instead of with $r^{-1}$. Here, $c$ denotes the speed of light and $t$ denotes the time that light takes to go from the magnetic-dipole object to the distance $r$ from the object. This interpretation has consistency with the notion that the relevant quadrupole component of the electromagnetic field associates with an object that people might characterize as having the properties of a magnetic dipole.)

2.1.4. We extend our modeling to include extrinsic properties of objects.

We deploy the symbol PROP to associate with $\Sigma g'$ solutions that we associate with intrinsic properties of objects. We deploy the symbol CURR to associate with $\Sigma g'$ solutions that we associate with currents of properties.

We anticipate extending the notions of PROP and CURR to apply widely regarding modeling regarding LRI. We anticipate that, for each LRI PROP solution, there is an LRI CURR solution.

Notions of three degrees of freedom seem to pertain regarding solutions that table 2 shows.

The following examples - of three degrees of freedom - pertain regarding 1g' solutions. Regarding
Regarding \( \Sigma = 4 \) symbol 0 is a placeholder for an unused pair, other solutions than \( 2g_2 \) can associate with gravitational effects that dominate gravitational effects that associate with \( 2g_2 \). For large-scale gravity, \( 2g' \) solutions other than \( 2g_2 \) term 3-vector associates with that rotation. (Regarding general relativity, each of \( 2g_1'2'3'4' \) and \( 2g_1'2'3'4' \) might associate with aspects of rotational frame dragging.) For gravity produced by an object like the Sun, \( 2g' \) solutions other than \( 2g_2 \) associate with adjustments with respect to the gravity that associates with \( 2g_2 \). Regarding large-scale gravitation, \( 2g' \) solutions other than \( 2g_2 \) can associate with gravitational effects that dominate gravitational effects that associate with \( 2g_2 \).

Table 1: \( \Sigma = |l_2| = |\sum_{\ell<0}(\pm l_\ell)| \) solutions, assuming that \( 1 \leq l_\ell \leq l_{\text{max}} \leq 4 \) and that no two values of \( l_\ell \) are the same. The columns labeled \( l_1 \) through \( l_4 \) show contributions toward expressions \( l_\ell = \sum_{\ell<0}(\pm l_\ell) \). In those four columns, the symbol 0 is a placeholder for an unused pair, \( -l_\ell \) and \( +l_\ell \), of values. The symbol \( n_{\ell<0} \) denotes the number of times the symbol \( 0 \) associates with an \( l_\ell \) for which \( 1 \leq l_\ell \leq l_{\text{max}} \). The symbol \( n_\Gamma \) denotes the number of elements in the list \( \Gamma \). For each row, there are \( 2^{n_{\ell<0}} \) possible ways to assign signs regarding the set of \( n_{\ell<0} \) terms. There are \( 2^{n_\Gamma} \) expressions of the form \( \Sigma = |l_2| = |\sum_{\ell<0}(\pm l_\ell)| \). The \( \Sigma \) column shows values of \( \Sigma \) that associate with solutions. For example, for \( l_{\text{max}} = 2 \) and \( \Gamma = 1 \), the two solutions feature, respectively, \( \Sigma = 2 \) (as in \( 1 = |1 + 2| \)) and \( \Sigma = 3 \) (as in \( 3 = |1 + 1 + 2| \)). The number \( n_{3g_\Gamma} \) equals \( 2^{n_\Gamma} - 1 \) and states the number of solutions. The column for which the one-word label is notion refers to the number of solutions. For monopole, one solution pertains. For dipole, two solutions pertain. For quadrupole, four solutions pertain. For octupole, eight solutions pertain. For the case of octupole, each one of \( \Sigma = 2 \) and \( \Sigma = 4 \) associates with two solutions. Regarding \( \Sigma = 2 \), \( |1 + 1 - 2+3+4| = 2 = |1 + 1 + 2 - 3+4| \). Regarding \( \Sigma = 4 \), \( |1 + 2 + 3 + 4| = 4 = |1 + 1 + 2 - 3+4| \).

Table 2: Interpretations - regarding properties of an object - regarding \( 2g' \) solutions for which \( 1 \leq \Sigma \leq 2 \) and \( 1 \leq l_{\text{max}} \leq 4 \). We suggest the following notions: A \( 1g_1 \) associates with a component - of the electromagnetic field that the object produces - that associates with the object's charge. The word scalar associates with this solution. A \( 1g_1'2' \) associates with the object's magnetic field. An axis associates with that field. The one-element term 3-vector associates with this solution. (For a bar magnet, the notions of change and rotation do not necessarily pertain.) A \( 1g_1'2'3'4' \) associates with a combination of magnetic field and rotation (over time) of the axis of the magnetic field. (The Earth is an object for which the axis of rotation does not equal the axis of the magnetic field.) The one-element term 3-vector associates with that rotation. \( 2g_2 \) associates with the object's mass. The word scalar associates with this solution. A \( 2g_2'4' \) associates with rotation of the object's mass. An axis associates with that rotation. The one-element term 3-vector associates with this solution. (Regarding general relativity, this solution associates with aspects of rotational frame dragging.) A \( 2g_1'2'3'4' \) associates with a non-spherically symmetric distribution of mass. A \( 2g_1'2'3'4'v \) associates with rotation of a non-spherically symmetric distribution of mass) around a minor axis of moment of inertia. The one-element term 3-vector associates with that rotation. (Regarding general relativity, each of \( 2g_1'2'3'4'v \) and \( 2g_1'2'3'4'w \) might associate with aspects of rotational frame dragging.) For gravity produced by an object like the Sun, \( 2g' \) solutions other than \( 2g_2 \) associate with adjustments with respect to the gravity that associates with \( 2g_2 \). Regarding large-scale gravitation, \( 2g' \) solutions other than \( 2g_2 \) can associate with gravitational effects that dominate gravitational effects that associate with \( 2g_2 \).
l_{g1'2}, three degrees of freedom pertain. Two degrees of freedom associate with the orientation of the magnetic moment 3-vector. One degree of freedom associates with the magnitude of the magnetic moment 3-vector. Compared to l_{g1'2}, l_{g1'2'4} has three more degrees of freedom. Two degrees of freedom associate with the orientation of the angular velocity 3-vector. One degree of freedom associates with the magnitude of the angular velocity 3-vector.

Regarding each of the solutions that table 2 shows, l_{o} = 4 seems to associate - regarding rotation - with three degrees of freedom.

We suggest that - for some aspects of our modeling - three degrees of freedom, mathematics associating with two one-dimensional harmonic oscillators, and mathematics associating with the group SU(2) associate with each other. (For integers l such that l ≥ 2, reference [25] interrelates mathematics associating with l one-dimensional harmonic oscillators and mathematics associating with the group SU(l).) Here, we consider that one oscillator might associate with boson-like excitations regarding a relevant aspect that associates with the relevant value of −l_{o}. The other oscillator might associate with boson-like excitations regarding a relevant aspect that associates with the relevant value of +l_{o}. The number of generators of the group SU(2) is three.

To explore CURR solutions, we want to add three degrees of freedom that associate with the CURR aspects of PROP-and-CURR 4-somes. (We use the one-element term 4-some and not the one-element term 4-vector. For modeling centric to special relativity and scalar PROP aspects, the notion of 4-vector might be appropriate. However, the following notions pertain. This essay discusses PROP aspects that do not necessarily associate with the notion of scalar. This essay includes CURR aspects that - depending on choices regarding kinematics modeling - do not necessarily need to comport with special relativity.) We posit that modeling - regarding the three degrees of freedom - associates with one l_{o}.

Regarding CURR solutions that associate with PROP modeling for which l_{max} ≤ 4, we posit that 8 ∈ Γ associates with velocity.

The notion that 8 ∈ Γ associates with velocity extends a series that seems to pertain regarding properties. The series includes charge, mass, intrinsic angular velocity, and velocity. For some of our modeling regarding electromagnetism, 1 ∈ Γ associates with charge. For some of our modeling regarding gravity, 2 ∈ Γ associates with mass. For some of our modeling, 4 ∈ Γ associates with intrinsic angular velocity (or - associating with some modeling - with intrinsic angular momentum). For some of our modeling for which l_{max} = 8, 8 ∈ Γ associates with extrinsic velocity.

Each l_{o} in the series 1, 2, 4, and 8 associates with the notion that log_{2}(l_{o}) is an integer. We explore notions regarding other values of l_{o}.

We discuss notions regarding l_{o} = 3. l_{g1'2} is a PROP solution that associates with intrinsic (nominal) magnetic moment. (See table 2.) Here, Σ = 1 and Γ = 1'2 pertain. For Γ = 1'2, Σ = 3 can pertain. We anticipate that l_{g1'2} is a PROP solution that associates with intrinsic anomalous magnetic moment. (Perhaps, preview table 4.) People measure anomalous magnetic moments for charged leptons (which are elementary fermions). For charged leptons, anomalous magnetic moments vary with fermion flavour. For some modeling, this essay associates - at least indirectly - l_{o} = 3 with (at least) the property of flavour for leptons. (The word leptons associates with some - but not all - elementary fermions. Perhaps, preview discussion related to table 23. This essay does not pursue notions that similar modeling associating with l_{o} = 3 might associate with aspects beyond lepton flavour.)

Regarding CURR solutions that associate with PROP modeling for which l_{max} ≤ 4, we posit the following. l_{o} = 7 associates (as does l_{o} = 1 for PROP modeling) for some solutions with charge. l_{o} = 6 associates (as does l_{o} = 2 for PROP modeling) for some solutions with mass. l_{o} = 5 associates (as does l_{o} = 3 for PROP modeling) with a function of lepton flavour.

2.1.5. We discuss notions that associate with l_{max} values that exceed eight.

Modeling above associates with the following notions. l_{max} = 4 for PROP solutions. l_{max} = 8 for CURR solutions. No one solution associates with both PROP and CURR. PROP-and-CURR solution pairs associate with 4-somes. l_{o} = 8 associates with velocity. Within a PROP-and-CURR pair, modeling associates the velocity with the notion of something that exhibits the property.

We explore adding three new degrees of freedom based on the following notions. No solution associates with both PROP and CURR. PROP solutions, l_{max} = 16 and, thus, l_{o} = 16 ∈ Γ. For CURR solutions, l_{o} = 16 ∈ Γ. l_{o} = 32 ∈ Γ and l_{max} = 32. (Perhaps, preview table 3 table 7 and table 8.)

Along with charge, mass, internal angular velocity (or internal angular momentum), and velocity, people measure or infer - regarding objects - energy. Per discussion above regarding a series of l_{o} for which log_{2}(l_{o}) is an integer, we posit that - for PROP solutions - l_{o} = 16 ∈ Γ associates with energy. We posit that - for modeling that comports with special relativity - l_{o} = 32 ∈ Γ associates with momentum.
Table 9 extends Table 2 and lists PROP and CURR $\Sigma g$ solutions, for which $1 \leq \Sigma \leq 4$ and $l_{\max} \leq 16$ for PROP $\Sigma g$ solutions. Elsewhere, we discuss the extent to which $3g1$ solutions might associate with an elementary particle and the extent to which $4g1$ solutions might associate with an elementary particle. (Perhaps, preview Table 9.)

Table 4 lists some $\Sigma g'$ solutions for which we posit relevance. Table 4 previews the notion that $1g3/4$ associates with - at least - depletion (via interactions with hydrogen-like atoms) of CMB (or, cosmic microwave background radiation) by ordinary matter and some dark matter. (Perhaps, preview Table 20.) Table 4 previews the notion that $3g1/2$ associates with modeling regarding anomalous magnetic moments. (Perhaps, preview Table 9.) For $3g1/2$, two CURR solutions pertain.

2.1.7. We provide perspective about modeling that associates with attractive and repulsive components of gravity.

We explore the extent to which each $2g'$ PROP solution associates with gravitational attraction and the extent to which each $2g'$ PROP solution associates with gravitational repulsion. We suggest results, based on generalizing from a series of cases.

We consider modeling regarding an object - object $A$ - and the gravity that object $A$ produces. We consider an object $B$ that interacts with the gravity that object $A$ produces. We assume that, relative to object $B$, object $A$ does not move.

We include cases for which PROP solutions can pertain for components of object $A$ or for the entire object.

One case associates with object $A$ associating with the notion of a point mass. The PROP $l_{\max}$ is two. Object $A$ has no internal components. The CURR solution $2g6/8$ associates with the motion of object $A$ and, per an assumption, is zero.

One case associates with the notion (regarding object $A$) of a non-rotating spherically symmetric distribution of mass. Object $A$ has internal components. For each component, we assume that modeling based on a PROP $l_{\max}$ of two suffices. The $2g2$ solution pertains. The CURR solution $2g6/8$ associates with motion of the component. Across the components, the motions of components might help to overcome internal gravitational collapse. (For example, for some objects, one might consider that the motions associate with thermal energy.) Across the components, the contributions to $2g6/8$ average to zero. The gravitational mass - which associates with $2g2$ for the object - associates with the sum of the energies that associate with the PROP $2g2$ solutions for the components. Object $B$ senses no first-order effects that would associate with $2g6/8$.

One case associates with the notion of a non-rotating non-spherically-symmetric distribution of mass. Here, we assume that three new (compared to the previous case) degrees of freedom associate with a magnitude and axis that associate with a maximal moment of inertia for object $A$ and that three other new (compared to the previous case) degrees of freedom might associate with a magnitude and axis that associate with a minimal moment of inertia for object $A$. The PROP solutions $2g2$ and $2g1/2$-3 pertain regarding object $A$. Over time, object $A$ might evolve to become more spherically symmetric. Energy that associates with having maintained at least one non-zero moment of inertia (which associates with $2g1/2$-3) would drain from the $2g2$ for object $A$. Independent of such possible evolution and compared to the previous case, this case illustrates the notion that the relevance of the $2g1/2$-3 solution associates with increased (compared to the previous case) $2g2$ and therefore with more (compared to the previous case) gravitational attraction (as experienced by object $B$).

The previous two cases illustrate the notion that for a $2g'$ PROP $\Gamma$ solution for which $4 \notin \Gamma$, $4 \notin \Gamma$ associates with gravitational attraction.

One case associates with the notion of a uniformly rotating spherically symmetric distribution of mass. This (hypothetical) object $A$ does not exhibit oblateness. For this case, one angular velocity $\omega$ pertains. The angular velocity is with respect to an axis that runs through the center of object $A$. The angular velocity pertains regarding each component of object $A$. The angular velocity associates with three degrees of freedom - two of which associate with the axis that associates with $\omega$ and one of which associates with the magnitude of $\omega$. The PROP solutions $2g2$ and $2g2/4$ pertain. The CURR solutions $2g6/8$ and $2g2/4$-8 pertain. From the perspective of an object $B$ that does not lie on an extension of the axis, the values of the $2g2/4$-8 for the components do not necessarily sum to zero. The gravitational mass - which associates with $2g2$ - for object $A$ associates with the sum of the energies that associate with the PROP $2g2$ solutions for the components.

If the hypothetical object $A$ (from the previous case) existed in nature, object $A$ would tend (over time) to become oblate. The transition process would release - from $2g2$ - energy that, in effect, laid maintained a lack of natural oblateness.

One case associates with the notion of the so-called natural oblateness that we just posited.

The last two cases illustrate the notion that, for modeling based on $2g'$ PROP solutions, $4 \in \Gamma$ associates with reducing gravitational effects and thereby associates with gravitational repulsion. Specifically, for a $2g1/2$ and a $2g2$, for which $2 \in \Gamma_a$, $2 \in \Gamma_b$, $4 \notin \Gamma_a$, and $\Gamma_b$ equals (in effect) $\Gamma_a/4$.  

15
Table 3: PROP and CURR $\Sigma^g$ solutions, for which $1 \leq \Sigma \leq 4$ and $l_{\text{max}} \leq 16$ for PROP $\Sigma^g$ solutions. Table 3 extends table 2 so as to include - for each PROP $\Sigma^g$ solution - a CURR $\Sigma^g$ solution. For example 1g7/8 satisfies $\Sigma = 1$ and associates with - for an object that produces an electromagnetic field - the charge-current 3-vector that complements the scalar charge that associates with PROP and with 1g1. No one $\Sigma^g$ solution associates with both PROP and CURR. The symbol $n_{\Gamma, \text{PROP}}$ denotes the number of elements in the $\Gamma$ that associates with PROP. Table 3 lists an RDF - or radial dependence of force - for each PROP solution. For a CURR $\Sigma^g$ solution, the RDP (or, radial dependence of potential) equals $\Xi^{-1}$ times the RDP for the associated PROP $\Sigma^g$ solution. For each one of PROP and CURR, the RDF equals $\Xi^{-1}$ times the RDP. For example, for each of 1g1 and 2g2, the RDF is $\Xi^{-2}$, which in $r^{-2}$. Table 3 shows properties - of objects that produce $\Sigma^g$ components of $\Sigma^g$ - that associate with the PROP solution. The table attempts to use familiar symbols. The table associates the symbols with phrases. The symbol TBD denotes at least one of the three-word phrase to be determined and the three-word phrase to be discussed. (Regarding 1g1/2/48/16, perhaps see discussion related to table 2. Regarding 2g1/2/3/4/8/16 and 2g1/2/3/4/8/16, perhaps see discussion related to table 9.)

</table>
the following notion pertains. Effects that associate with \( 2\Gamma \) decrease the gravitational attraction that associates with \( 2\gamma \).

Table 3 pertains regarding modeling that has bases in \( 2\gamma \) PROP solutions.

2.1.8. We discuss modeling that might associate with CURR solutions for which \( \ell_{max} = 32\).

We anticipate modeling - in which some \( \Sigma = 0 \) solutions associate with simple elementary particles - in which (for at least the known elementary particles) the following notions pertain regarding QFT (or, quantum field theories). (Perhaps, preview table 7 and table 8.) Simple particles for which CURR modeling associates with \( \ell_{max} = 8 \) can model (for some circumstances) as not entangled. Simple particles for which CURR modeling associates with \( \ell_{max} = 32 \) seemingly do not model (for any circumstances) as not entangled.

For convenience, we associate the word free with aspects that associate with modeling that associates with CURR solutions for which \( \ell_{max} = 8 \). For convenience, we associate the word entwined with aspects that associate with modeling that associates with CURR solutions for which \( \ell_{max} = 32 \). We chose the word entwined so as to avoid using the word entangled. (In some circumstances, free elementary particles model as entangled. An example features an electron that is part of an atom.)

2.1.9. We discuss possible limits on the applicability of \( \Sigma g' \) solutions.

This essay suggests that - regarding \( \Sigma g' \) solutions that might have relevance regarding modeling for \( \Lambda \) - that \( \Sigma \) does not exceed four. The suggestion associates with an extrapolation regarding data pertaining to the relative strengths of electromagnetism and gravity. (Perhaps, preview table 15.) That extrapolation suggests that a \( 5\gamma \) solution would associate with a force strength of zero. We posit that, if \( 5\gamma \) associates with zero force strength, each \( \Sigma g' \) solution for which \( \Sigma \geq 5 \) is not relevant regarding \( \Lambda \) physics. The suggestion also associates with the notion that - for PROP solutions \( \Sigma g\Gamma \) for which \( \Sigma \neq 0 - 5 \notin \Gamma \).

We discuss \( 3\gamma \) solutions and \( 4\gamma \) solutions.

Regarding \( 3\gamma \), table 3 shows a \( 3\gamma 2'3'4' \) solution. There is no associated same-\( \Sigma \) \( \Sigma g' \) other solution to which one can add \( \ell_o = 4 \) to obtain the subject solution. Regarding \( 4\gamma \), table 3 shows a \( 4\gamma 1'2'3'4' \) solution and a \( 4\gamma 1'2'3'4' \) solution. There is no associated same-\( \Sigma \) \( \Sigma g' \) other solution to which one can add \( \ell_o = 4 \) to obtain either the \( 4\gamma 1'2'3'4' \) solution or the \( 4\gamma 1'2'3'4' \) solution. To the extent that - for \( \Lambda \) PROP solutions - \( 4 \in \Gamma \) associates with rotation, the only \( 3\gamma \) and \( 4\gamma \) solutions that are relevant to \( \Lambda \) physics might be \( 3\gamma 3 \) and \( 4\gamma 4 \).

The notion that only \( 3\gamma 3 \) is relevant for the case of \( \Lambda \) plus PROP plus \( 3\gamma \) seems to be consistent with the notion that a \( 3\gamma 3 \) interaction associates with the flavour of one elementary fermion. Notions of rotation or spatial distribution for the property of flavour are not necessarily relevant regarding one elementary fermion. Notions of interactions with the flavours of more than one fermion in an object that contains more than one elementary fermion are not necessarily relevant.

Similarly, the notion that only \( 4\gamma 4 \) is relevant for the case of \( \Lambda \) plus PROP plus \( 4\gamma \) would seem to be consistent with a notion that a \( 4\gamma 4 \) interaction associates with the scalar \( S \) that associates with one elementary particle.

We discuss possible limits regarding \( 2\gamma \) solutions.

We consider two objects that are some distance apart from each other. We consider doubling linear dimensions - that is doubling the distance between the objects and doubling the diameters of the objects - while maintaining, for each object, a constant mass per unit volume. A PROP RDF \( \Xi^{-6} \) force after the doubling of linear dimensions equals the PROP RDF \( \Xi^{-6} \) force before the doubling of linear dimensions. Possibly, this invariance regarding scaling suggests reasons not to pursue - regarding interactions between pairs of large objects - modeling regarding PROP RDF \( \Xi^{-1} \) for which \( l \) exceeds six.

Regarding \( 2\gamma \), table 3 shows two PROP solutions - \( 2\gamma 1'2'3'8'16 \) and \( 2\gamma 1'2'3'4'8'16 \) - for which \( \ell_{max} = 32 \) associates with the respective CURR solutions. The PROP solution \( 2\gamma 1'2'3'8'16 \) associates with energy and with an RDF of \( \Xi^{-6} \). Solution \( 2\gamma 1'2'3'8'16 \) associates with attraction. (See table 7.) The PROP solution \( 2\gamma 1'2'3'4'8'16 \) associates with changes in energy and with an RDF of \( \Xi^{-7} \). Solution \( 2\gamma 1'2'3'4'8'16 \) associates with repulsion. (See table 13.)

This essay notes - but does not much discuss - the notion that the PROP solution \( 2\gamma 1'2'3'4'8'16 \) might associate with repulsion within a small object and with aspects such as radioactive decay and thermal radiation. (See table 8. Perhaps, preview table 2.) Also, this essay does not further discuss possible associations of the notion of \( 2\gamma 1'2'3'4'8'16 \) repulsion with notions such as entropy and arrow of time.)

We discuss possible limits regarding \( 1\gamma \) solutions.

Regarding \( 1\gamma \), table 3 shows one PROP solution - \( 1\gamma 1'2'4'8'16 \) - for which \( \ell_{max} = 32 \) associates with the respective CURR solution. Possibly, to the extent that a limit that associates with PROP RDF \( \Xi^{-6} \) pertains regarding \( 2\gamma \), no \( 1\gamma \) PROP RDF \( \Xi^{-l} \) solution for which \( l \geq 7 \) pertains regarding modeling for electromagnetic interactions between pairs of objects.
2.1.10. We list known and possible LRI elementary bosons.

Table 6 shows solutions that might associate with LRI (or, long-range interaction) elementary particles.

2.1.11. We develop modeling that matches and suggests all elementary particles (other than bosons that intermediate long-range forces) that this essay discusses.

We explore the notion that solutions for which \( \Sigma = 0 \) associate with known and possible non-\( \Sigma G \) elementary particles (or, non-LRI elementary particles). Based on arithmetic, for each \( \Sigma = 0 \) solution, \( n_f \) is at least three. We associate the symbol SRI (as in short-range interaction or as in elementary boson that does not associate with a long-range interaction) with non-\( \Sigma G \) elementary bosons. We associate the symbol ELF (as in elementary fermion) with fermion elementary particles.

For each \( \Sigma = 0 \) solution, there are two expressions of the form \( 0 = l_\Sigma = \sum_{o \in O} (\pm l_o) \). (See discussion related to table 4.) For each solution for which \( \Sigma > 0 \), there are two expressions. (See discussion related to table 5.) For each solution for which \( \Sigma > 0 \), we associate one expression with left-circular polarization. For each solution for which \( \Sigma > 0 \), we associate one expression with right-circular polarization. For each \( \Sigma = 0 \) solution, we posit that one expression associates with the notion of left-handedness and the other expression associates with the notion of right-handedness.

Table 7 shows \( \Sigma G \) solutions that might associate with elementary bosons that are not \( \Sigma G \) bosons. (Reference [10] discusses the inflaton particle.)

Table 8 shows \( \Sigma G \) solutions that might associate with elementary fermions.

2.1.12. We preview aspects regarding the entwined simple elementary particles that we suggest and people have yet to find.

Each of table 7 and table 8 shows simple particles that - within the context of our work - model as entwined.

After very early in the timeline that concordance cosmology features, 0.5R particles might exist only in hadron-like particles that include 1U (or, gluon) particles and that are somewhat analogs to known hadrons. In the very early universe, 0.5R and 1U particles might model as being components of so-called seas.

After very early in the timeline that concordance cosmology features, 0I particles might contribute effects that are negligible compared to effects that other bosons contribute. In the very early universe, 0I particles might fulfill the role that concordance cosmology posits for the so-called inflaton.

Regarding any time during the cosmological timeline, modeling might associate with the notion that 1J particles might intermediate Pauli repulsion between similar fermions. (Here, the fermions are not necessarily elementary fermions.)

2.2. Isomers and dark matter

This unit suggests that most dark matter has bases in five isomers of the elementary particles that are not \( \Sigma G \) elementary particles and that ordinary matter has bases in one (other) isomer of most elementary particles that are not \( \Sigma G \) elementary particles.

2.2.1. We discuss the notion that, if nature includes only one isomer of each elementary particle, modeling might not suffice to explain known data about dark matter.

Discussion above points to two types of elementary particles that would measure as dark matter or that would provide a basis for dark matter. 0.5M fermions associate with the notion of free and would measure as dark matter. 0.5R fermions associate with the notion of entwined. Hadron-like particles containing gluons and 0.5R fermions would contain no charged particles and would measure as dark matter.

We use the term DMAI to denote stuff that has bases in 0.5M elementary fermions or in 0.5R elementary fermions. DM abbreviates the two-word term dark matter. AI abbreviates the two-word term all isomers. (Here, we allude to a notion of multiple isomers of some elementary particles. For the moment we assume that nature includes just one isomer.)
Table 6: Solutions that might associate with LRI (or, long-range interaction) elementary particles. The symbol $n_{EP}$ denotes the number of elementary particles. Items in the table show in parentheses might depend on future data or on interpretations of vocabulary and modeling - associate with elementary particles. TBD denotes the three-word phrase to be determined.

Table 7: Solutions that might associate with non-$\Sigma_g$ elementary (or, with SRI) bosons. Each column with label $0 = \ldots$ shows a calculation that produces the $\Sigma = 0$ that associates with a $\Sigma_g$ solution. Each integer that the calculation includes is a member of $\Gamma$. No other integer is a member of $\Gamma$. The symbol $n_{\text{PROP}}$ denotes the number of $l_0$ that appear in the $\Gamma$ for the PROP solution. The symbol $n_{\text{CURR}}$ denotes the number of elementary particles. We posit that the aye (or, all bosons) associates with notions of an inflation. Inflations would be zero-sum zero-charge bosons that might have played key roles during a hypothesized inflationary epoch, early in the evolution of the universe. The $W$ boson is the only charged elementary boson. In the table, only one PROP solution does not have - as members of $\Gamma$ - all of $1, 3$, and $4$. Based on the previous two sentences, we associate $\Sigma_g = 3$ with the $W$ boson and we associate $\Sigma_g = 4$ with the $Z$ boson. We posit that, paralleling aspects of some $1g^1$ CURR solutions, for the CURR solution that associates with the $W$ boson, $l_0 = 7$ associates with charge. We posit that, paralleling aspects of some $1g^1$ CURR solutions, for the CURR solution that associates with the gluons, $l_0 = 5$ associates with some elementary fermions and with color charge. We posit that the ane (or, 1J) boson associates with notions of Pauli repulsion. Pauli repulsion associates with the notion that two fermions (whether elementary fermions or not elementary fermions) cannot occupy the same state. Pauli repulsion associates with repulsive aspects of the residual strong force. We suggest the possibility that, but do not necessarily require that, - with respect to the Standard Model notion that SU(3) symmetry associates with the strong interaction - the $W$ boson might (for some modeling, perhaps yet to be determined) associate with the identity operator that SU(3) represents for the gluons (which transmit color charge) exclude. We suggest that mutual - for gluons and $W$ bosons - association with the strong force associates with the notion that the 1J PROP solution equals the 1U PROP solution. We suggest that the $W$ boson can interact with each fermion elementary particle, regardless of whether the notion of color charge pertains for the elementary fermion. We posit that the $W$ boson can interact with each fermion non-elementary-particle object. In each of the leftmost two columns in the table, two uses of a pair of the symbol $\Gamma$ points to dual use of a solution.

Table 8: Solutions that might associate with elementary fermions (or, ELF elementary particles). We posit, regarding PROP $0g$ solutions, that 6 $\in \Gamma$ associates with elementary fermions. (The might-be three degrees of freedom that might associate with $l_0$ might associate with three choices regarding flavour for elementary fermions.) Paralleling notions pertaining to non-$\Sigma_g$ elementary bosons, if, and only if, each of 1, 3, and 4 is a member of $\Gamma$, an elementary particle that associates with $\Sigma_g$ has zero charge. The symbol $n_{EP}$ denotes the number of elementary particles. We discuss solutions that associate with quarks. 0.5Q is the only known particles for which $0 < Q < 1$. Here, $Q$ denotes the magnitude of the charge, in units of $|q_1|$, $q_1$ denotes the charge of the electron. The notion of PROP solution associates with each of the following two solutions: 0 = |1 - 3 - 6 - 8 + 16|, and 0 = |+ 2 - 4 - 6 - 8 + 16|. The notion of CURR solution associates with each of the following two solutions: 0 = |+ 1 - 3 - 6 - 8 + 16| and 0 = |+ 2 - 4 - 6 - 8 + 16| + 32|. Two possibilities exist. For one possibility, the following two sentences pertain. Quarks with one magnitude of charge associate with one of the PROP solutions and one of the CURR solutions. Quarks with the other magnitude of charge associate with the other one of the PROP solutions and the other one of the CURR solutions. For the other possibility, the following three sentences pertain. One of the PROP solutions and one of the CURR solutions associate (for modeling purposes) with $Q = 1/2$. The other one of the PROP solutions and the other one of the CURR solutions associate (for modeling purposes) with $Q = 1/2$. One linear combination of the two pairs associates with $Q = (1/2) + (1/6) = 2/3$ and another linear combination of the two pairs associates with $Q = (1/2) - (1/6) = 1/3$. (Perhaps, preview aspects, such as $Q = 1/2$, of table 2 and table 3)

We use notation of the form DM:OM to denote an inferred ratio of DM effects to OM effects. OM abbreviates the two-word term ordinary matter.

Measurements suggest seemingly significant DM:OM ratios. (For information about the ratios and for relevant references, perhaps preview table 20 and discussion related to table 20.) Ratios of approximately $5^+1$ pertain regarding densities of the universe, galaxy clusters, and many galaxies. Seemingly significant ratios of $1^+:0^+$ and $\sim4^+:1$ pertain regarding some galaxies. A ratio of $1:1$ might pertain regarding some depletion of cosmic microwave background radiation (or, CMB). We know of no other such seemingly significant DM:OM ratios.

We suggest that, if DMAI is the only type of dark matter, DMAI might not suffice to explain various seemingly significant ratios of dark matter to ordinary matter. We suggest that the notion of DMAI might not suffice to explain dark matter.

2.2.2. We discuss the notion that nature includes six isomers of each elementary particle that does not intermediate a long-range force.

We suggest that nature includes six isomers of the SRI and ELF elementary particles - or, six isomers of the set of elementary particles that associates with all non-G elementary bosons and all elementary fermions. (See table 7 and table 8.) One isomer associates with ordinary matter plus one isomer of DMAI. That one isomer of DMAI measures as dark matter. Each one of the other five isomers of the set of non-SG elementary particles measures as dark matter. Regarding densities of the universe, the five isomers of non-DMAI that measure as dark matter associate with the 5 in the DM:OM ratio of $5^+1$. The six isomers of DMAI associate with the + in the DM:OM ratio of $5^+1$.

We use a two-word phrase isomer number to denote one isomer. Here, number can be any one of zero, one, ..., and five. We associate the two-word term isomer zero with the isomer that includes ordinary matter. We use the two-word phrase alt isomer to denote any one of the five isomers that does not associate with ordinary matter.

2.2.3. We discuss modeling - regarding simple elementary particles - that might associate with the notion of six isomers of simple elementary particles.

Table 7 and table 8 point to all simple elementary particles that this essay features. With one exception (regarding quarks, in table 8), for each PROP solution, each one of 1 $\in \Gamma$ and 3 $\in \Gamma$ pertains. We suggest that - relative to one of those two membership (in $\Gamma$) associations, the other membership (in $\Gamma$) association associates with three choices. (Here, the notion of three choices associates - for other circumstances - with notions that an $l$, associates with three degrees of freedom. Perhaps, see discussion - regarding table 8, regarding 6 $\in \Gamma$ and three flavours.) Each PROP solution in table 7 and table 8 associates with two expressions. We posit that one expression associates with left-handedness and one expression associates with right-handedness. (Perhaps, preview discussion related to table 16.) We point to the possibility that the combination of three choices and two handednesses associate with six isomers. This essay uses this notion regarding the six isomers. (Perhaps, preview discussion related to table 16.)

We think that the exception (regarding quarks, in table 8) regarding the 0g2:4:6:8:16 solution might point to making a choice between two notions that table 8 mentions. Solution 0g1:3:6:8:16 would associate mathematically with $Q = 1/2$. Solution 0g2:4:6:8:16 would associate mathematically with $Q = 1/6$.

2.2.4. We discuss modeling - for long-range interactions - that associates with the notion of six isomers of simple elementary particles.

All six isomers produce and interact with a common notion of gravity. We suggest that one instance of 2g2 mediates interactions between all six isomers. We say that one instance of 2g2 has a reach of six, as in six isomers. We suggest that each isomer associates with its own instance of 1g1 and its own instance of 1g1'. We say that each instance of 1g1 has a reach of one, as in one isomer. Each instance of 1g1' has a reach of one. Each isomer - including the ordinary matter isomer - scarcely interacts with any other isomer via electromagnetism.

We address the topic of reach for each $\Sigma g \Gamma$ to which table 4 alludes. Based on the reach of 1g1 and the reach of 1g1', we suggest that $n_{o0} = 0$ associates with a reach of one. Based on the reach of 2g2, we suggest that $n_{a0} = 1$ associates with a reach of six. We posit that, for $n_{a0} \geq 1$, the reach of one instance of a relevant PROP $\Sigma g \Gamma$ equals the number of generators of the group $SU(7)$ divided by the number of generators of the group $SU(2n_{a0}+1)$. For an integer $l$ that is at least two, the number of generators of the group $SU(l)$ is $l^2 - 1$. The reach that associates with $n_{a0} = 2$ is two. The reach that associates with $n_{a0} = 3$ is one. The number of instances of a PROP $\Sigma g \Gamma$ component of a $\Sigma G$ elementary particle is six divided by the reach that associates with the PROP $\Sigma g \Gamma$ solution.

We assume that the reach of a CURR counterpart solution to a PROP $\Sigma g \Gamma$ solution is the same as the reach of the PROP $\Sigma g \Gamma$ solution.

We address the reach of the 2g1'2:3:8:16 PROP solution, which table 8 lists and table 1 does not list. For 2g1'2:3:8:16, each of 1, 2, and 3 appears in $\Gamma$ and 4 does not appear in $\Gamma$. We assume that $n_{a0} = 1$. The reach for 2g1'2:3:8:16 is six. Energy-
and-momentum 4-somes can associate with stuff - such as a galaxy cluster - that associates with all of the six isomers. Energy-and-momentum 4-somes can associate with stuff - such as a simple elementary particle - that associates with less than all of the six isomers.

We address the reach of the $2g1\cdot2'3'4'8'16$ PROP solution, which table 3 lists and table 1 does not list. For $2g1\cdot2'3'4'8'16$, each of 1, 2, 3, and 4 appears in $\Gamma$. We assume that $n_{00} = 0$. The reach for $2g1\cdot2'3'4'8'16$ is one. Energy-decay-and-momentum-change 4-somes might - if modeling based on them has physics relevance - associate with single-isomer stuff - such as an atomic nucleus.

Table 3 shows the reach ($\rho I$) for - and other information about - each one of some solutions that table 3 and table 4 list. Discussion that relates to table 3 and to table 6 suggests that some items that table 3 lists are not necessarily relevant to modeling that pertains to relevant physics. Table 6 does not include those not necessarily relevant items.

Regarding the notion of a reach, $\rho I$, of two, there are three instances of the PROP solution. We number the isomers so that one instance of the $1g3'4'$ solution intermediates interactions between isomer zero and isomer three. One instance of the $1g3'4'$ solution intermediates interactions between isomer one and isomer four. One instance of the $1g3'4'$ solution intermediates interactions between isomer two and isomer five.

We use notation of the form $\Sigma(\rho I)g\Gamma$ to denote a $\Sigma g\Gamma$ solution and the reach $\rho I$ that associates with one modeling use that features an instance of the solution. For example, $2(2)g2'4$ pertains regarding $2g2'4$. We extend use of such notation to non-LRI elementary particles. For non-LRI elementary particles, the reach is one and notation of the form $S(1)\Phi$ pertains.

We posit that - for each $\Sigma(2)g\Gamma$ solution - one instance of the solution intermediates interactions between isomer zero and isomer three. One instance of the solution intermediates interactions between isomer one and isomer four. One instance of the solution intermediates interactions between isomer two and isomer five.

We discuss notions regarding excitation and de-excitation of LRI fields (or, of $\Sigma G$ elementary particles).

An excitation associates with a value of $\Sigma$ and with a set of isomers. For example, consider an excitation that associates with active-gravitational properties of an ordinary matter star. The word active associates with the notion that the star generates gravity. The word gravitational associates with $\Sigma = 2$. The excitation might associate with the $2g2'$ solution, with the $2g2'4$ solution, or with another $2g$ solution. Because the star consists just of ordinary matter stuff, the set of isomers consists just of isomer zero.

A de-excitation associates with the notion of passive properties, with any same-$\Sigma \Sigma G$ solution and with a set of isomers that associates with the original excitation. We continue the previous example. Regarding $\Sigma = 2$, the word passive associates with the notion that an object interacts with gravity that other objects actively produce. Because $2g2'$ has a reach of six, any object can de-excite, via $2g2'$, the excitation that the example features. Because $2g1'2'3$ has a reach of one, only isomer zero stuff can de-excite, via $2g1'2'3$, the excitation. Because $2g2'$ has a reach of two, only isomer zero stuff or isomer three stuff can de-excite the excitation via $2g2'$.

Generally, ten types of de-excitations exist. One type consists of de-excitations that associate with reach-six solutions. Three types consist of de-excitations that associate with reach-two solutions. One of the three types associates with isomer zero and isomer three. Another one of the three types associates with isomer one and isomer four. The other one of the three types associates with isomer two and isomer five. Six types consist of de-excitations that associate with reach-one solutions. Each one of the six types associates with exactly one isomer.

We discuss excitations and de-excitations that associate with long-range forces produced by a galaxy that consists of stuff that associates substantially with each of the six isomers. (Perhaps, preview table 20.) We discuss electromagnetism. A one-isomer distant observer would directly sense mostly aspects that associate with the distant observer’s isomer. Here, most detection of photons would associate with the reach-one solutions $1g1'$ and $1g1'2$. (The observer might infer - from sensed data - aspects regarding the other five isomers and aspects regarding gravity.) Via aspects that associate with solutions such as $1g1'2'4$ (for which the reach is six) and $1g3'4$ (for which the reach
### Table 9: Reaches and other information regarding some solutions that associate with electromagnetism, gravity, 3G, and 4G. \( \rho \) denotes reach. \( \Sigma \in \Gamma \) associates with the symbol \( g' \). \( \Sigma \notin \Gamma \) associates with the symbol \( g'' \). NYN denotes not yet named. TBD denotes to be determined. Discussion related to table 23 provides information regarding the notion of anomalous magnetic moment.

is two), the one-isomer observer might directly sense aspects that associate with isomers other than the observer's isomer. (For example, the observer might sense hyperfine transitions associating with one isomer other than the observer's isomer. Here, \( 1(2)g3-4 \) is relevant. The observer might identify hyperfine spectrum lines. The observer would not necessarily know directly the extent to which each of the two relevant isomers contributed to the data the observer collects.) We discuss gravitation. We assume that the observer has adequate means for directly detecting gravity that the galaxy produces. The one-isomer distant observer would sense all of the galaxy's stuff via \( 2g2 \) (for which the reach is six). But the sensing of subtleties (such as rotation of stuff or irregular distributions of stuff) might associate with solutions (such as \( 2g2'4 \) and \( 2g1-2'3 \)) for which the reaches are less than six. (Perhaps, see table 2.) The one-isomer observer would not necessarily sense directly via \( 2G \) all of the subtleties.

### 3. Results

This unit discusses explanations for known data and discusses suggestions regarding possible data that people have not yet measured. The discussion includes explanations and suggestions regarding elementary particles, dark matter, galaxies, and the cosmos.

#### 3.1. Elementary particles

This unit lists elementary particles that associate with our modeling and discusses relationships between properties of elementary particles.

### 3.1.1. We list all elementary particles of which people know or that we suggest.

Table 10 consolidates and summarizes information about all elementary particles of which people know or that this essay suggests. (See table 8, table 7, and table 8.)

### 3.1.2. We explore relationships among properties of objects, elementary particles, and long-range interactions.

Table 11 discusses relationships between properties of elementary bosons. (Regarding the masses of the Higgs, Z, and W bosons, we used data that reference 8 provides.)

Table 11 points to possibly deeper (than people might otherwise suggest) relationships between the physics properties of spin, mass, and charge. (Also, regarding the non-zero mass elementary bosons, a notion that non-zero spin might associate with - in effect - reduction in mass seems not to be incompatible with discussion related to table 3.)

We turn our attention to properties of elementary fermions.

We consider hypothetical elementary fermions for which \( Q = 1 \). For some value of mass, the gravitational attraction between two identical such hypothetical elementary fermions would equal the electrostatic repulsion between the two fermions. Our work shows that a mass - so-called \( m(18, 3) \) - seems to have meaning beyond the notion that - for the mass \( m(18, 3) \) - gravitational attraction between two \( Q = 1 \) identical elementary fermions would be three-quarters of the electrostatic repul-
Table 10: Elementary particles. The symbol $Q$ associates with magnitude of charge. The columns labeled $Q > 0$ and $Q = 0$ have entries in the form of a name of one particle or a name of a set of more than one particle, followed (in parentheses) by a number of particles, followed by a symbol for the family of particles. NYN denotes not yet named. NYD denotes not yet detected. One might assert that people know of some NYD particles, at least indirectly. The word free associates with modeling that features PROP solutions for which $16 \notin \Gamma$. The word entwined associates with modeling that features PROP solutions for which $16 \in \Gamma$. Each $\Sigma G$ particle for which $\Sigma \leq 3$ associates with more than one PROP solution. For $1G$, some modeling (for example, regarding light in a laser cavity) might associate with entwined. (Perhaps, preview table 22.) Otherwise, for familiar circumstances, entwined aspects of $\Sigma G$ particles do not play prominent roles.

Table 11: Relationships between properties of elementary bosons. $Q$ denotes the magnitude of charge, in units of $|q_e|$. $m$ denotes mass, in units of $m_{Higgs}/17^{1/2}$ or in units of $m_Z/9^{1/2}$. $S$ denotes spin, as in the expression $S(S+1)h^2$. $l_{ms}$ equals $-1$ for $m > 0$ and equals 0 for $m = 0$. The sum is the sum of the numbers in the preceding four columns. Each sum is the square of an integer. For each nonzero mass particle, the integer equals $n_{PROP}$. (See table 7) There are no nonzero mass elementary bosons for which the integer equals one or two. (For a $\Gamma$ that includes just one value of $l_0$ or that includes just two values of $l_0$, $\Sigma \neq 0$ pertains.) NYN denotes the three-word phrase not yet named. Of the non-zero masses to which table 11 alludes, the most accurately known mass is that of the Z boson. Using the mass of the Z boson and numbers in table 11, one can calculate a nominal mass for the Higgs boson and a nominal mass for the W boson. The calculated mass for the Higgs boson differs from the experimentally determined mass by less than two (experimental) standard deviations. The calculated mass for the W boson differs from the experimentally determined mass by less than four (experimental) standard deviations. To the extent that one uses the notion that ruling out an equality requires a difference of at least five standard deviations, experimental results do not seem to rule out relationships that table 11 states.

sion between the two identical elementary fermions. (Perhaps, preview table 12 and table 13.)

Table 12 discusses relationships between properties of known charged elementary fermions. (Reference [8] provides the data that underlies table 12.)

Table 13 shows equations that underlie aspects of table 12. (Reference [8] provides the data that underlies table 13.)

3.1.3. We show modeling that might estimate the anomalous magnetic moment for the tau elementary particle.

We explore modeling regarding anomalous magnetic moments for 0.5C1 elementary particles (or, charged leptons).

Table 14 suggests the mass for the tau lepton, via the expression $a_\tau + a_{\phi \ell \phi}$. Here, $a_\tau$ varies with charge and would be a constant with respect to a choice between $c_l = e$ (for the electron), $c_l = \mu$ (for the muon), and $c_l = \tau$ (for the tau). Here, $a_\phi$ might vary only with mass. We assume that $a_\phi$ is $(\log(m_\phi/m_\ell))^2$. (Perhaps, compare with table 12 and with aspects - that exhibit squares of properties - of table 13.) The notion of squares of properties might associate with notions of self-interactions. Based on data that reference [8] provides regarding the electron and the muon, we calculate $a_\tau$ and $a_\phi$. Then, we calculate a value, $a_{\tau,\text{PM}}$, for $a_\tau$. Here, PM denotes the two-word term proposed modeling. PM associates with our work. Reference [27] provides, based on Standard Model modeling techniques, a first-order result - which we call $a_{\tau,\text{PM}}$ - for $a_\tau$. Here, SM denotes the two-word term Standard Model. The value of $a_{\tau,\text{PM}}$ results in a value of $(a_{\tau,\text{PM}} - a_{\tau,\text{SM}}) / a_{\tau,\text{SM}}$ of approximately $-0.00228$. Each of $a_{\tau,\text{PM}}$ and $a_{\tau,\text{SM}}$ comport with experimental data that reference [8] provides.

Regarding anomalous magnetic moments, this essay does not explore quantifying aspects that associate with higher-order Standard Model terms or aspects that might associate with the PROP solution $3g_1'2^4$. (Regarding the PROP solution $3g_1'2^4$, see table 1.)

3.1.4. We discuss the masses of neutrinos and of elementary fermions that we suggest.

Table 14 suggests rest energies that may pertain regarding the known 0.5N neutrinos and the suggested 0.5R arcs. This table extends aspects of table 12 and table 13. (Reference [8] provides data that underlies aspects of table 12, table 13, and table 14.)

Table 12 and table 13 might point to possibly deeper (than people might otherwise suggest) relationships between the physics properties of mass and charge.

We explore two alternatives regarding values of $d'(0)$, $d'(1)$, and $d'(2)$. (See table 13.) Changing these numbers would impact the calculated masses for quarks and the calculated suggested masses for arcs. (Changing those numbers would not impact the calculated masses for charged leptons.) Regarding each of the two alternatives, if one excludes one of three methods for estimating the mass of the top quark, the calculated mass for each of the six quarks is within five standard deviations of the experimental mass. (Reference [8] discusses the three methods.) For the third method for estimating the mass of the top quark, the value that we calculate for the mass of the top quark would be less than eleven standard deviations below the mass people have calculated.

One alternative has bases in the notions of $d'(-1) = 0^2/2^2$, $d'(0) = 1^2/2^2$, $d'(1) = -2^2/2^2$, and $d'(2) = -2(2 \times 3)/2^2$. For this alternative, the three arc rest energies would, respectively, be $\approx 8.14$ MeV, $m(1,3)c^2$, and $m(2,3)c^2$.

The other alternative has bases in the notions of $d'(0) \approx 0.264825$, $d'(1) = -2^2/2^2$, and $d'(2) = -2(2 \times 3)/2^2$. For this alternative, the three arc rest energies would, respectively, equal $m(1,3)c^2$, $m(1,3)c^2$, and $m(2,3)c^2$. Across the three 0.5C1 elementary fermions and the three 0.5R elementary fermions, $m(0,3)c^2$ would pertain once, $m(1,3)c^2$ would pertain twice, $m(2,3)c^2$ would pertain twice, and $m(3,3)c^2$ would pertain once.

We discuss possible masses for heavy neutrinos. For purposes of estimating or calculating masses, neutrinos associate with a value of $l_m$ for which $-6 \leq l_m \leq -3$. Charged leptons associate with $0 \leq l_m \leq 3$. If heavy neutrinos associate with $6 \leq l_m \leq 9$, a lower bound on rest energies for heavy neutrinos might be $m(6,3)c^2 = 8 \times 10^9$GeV, which might be large enough to comport with limits that associate with observations. (References [28] and [29] discuss limits that observations may set. People have not detected 0.5M particles.) To the extent the lower bound associated with $m(6,3)2c^2$, the lower bound would be $\sim 2.5 \times 10^9$GeV.

3.1.5. We discuss a possible limit regarding the spins of elementary particles that intermediate long-range interactions.

Table 15 suggests the possibility that - for LRI elementary particles $\Sigma G - \Sigma$ might be no greater than four.
the formula. Perhaps preview Table 14.)

classic elements, the known 0.5N neutrinos, and the suggested 0.5R arcs. (Regarding 0.5N neutrinos and 0.5R arcs, perhaps preview Table 14.)

Table 12: Values of \( \log_{10}(m_{\text{particle}}/m_e) \) for known charged elementary fermions. Regarding “flavour,” this table generalizes, based on terminology that associates with charged leptons and neutrinos. For example, people use the term electron-neutrino. The symbol \( l_f \) numbers the three flavours. The “\( l_f(0.5C_1) \)” terms pertain for fermions in the 0.5C_1 family. The symbol 0.5Q > 0 denotes the pair 0.5Q_{1/3} and 0.5Q_{2/3}. The “\( l_f(0.5Q > 0) \)” terms pertain for quarks or, elementary particles in the two families 0.5Q_{2/3} and 0.5Q_{1/3}. \( l_m \) is an integer parameter. The domain \(-6 \leq l_m \leq 18\) might have relevance regarding modeling. \( Q \) denotes the magnitude of charge, in units of \( |q_e| \). The family 0.5C_3 associates with \( Q = 1 \). The family 0.5Q_{2/3} associates with \( Q = 2/3 \). The family 0.5Q_{1/3} associates with \( Q = 1/3 \). Regarding the rightmost four columns, items show \( \log_{10}(m_{\text{particle}}/m_e) \) and - for particles that nature includes - the name of an elementary fermion. For each \( l_f \) case, no particle pertains. Each number in the column with label \( Q = 1/2 \) equals the average of the number in the \( Q = 2/3 \) column and the number in the \( Q = 1/3 \) column. The notion of geometric mean pertains regarding the mass of the \( Q = 2/3 \) particle and the mass of the \( Q = 1/3 \) particle. Regarding each \( l_f \) case, a formula for \( m_{(l_m, l_q)} \) calculates this number. Regarding the formula, the domain \( 0 \leq l_q \leq 3 \) pertains. Regarding Table 12, \( l_q = 3Q \) pertains. Table 13 shows the formula.

<table>
<thead>
<tr>
<th>Topic</th>
<th>Note</th>
</tr>
</thead>
</table>
| Arcs  | Our work suggests (but does not necessarily require) some specific masses for the three arc particles.\[ l_q = 0 \] This notion comports with the notion - for arcs - that \( Q = 0 \).\[ m(l_m, 0) = m(l_m, 1) \cdot (m(l_m, 1)/m(l_m, 2)) \] - This essay assumes this equation.\[ m(0, 0)c^2 \approx 10.7 \text{ MeV, } m(1, 0)c^2 \approx 6.8 \text{ MeV, } m(2, 0)c^2 \approx 102 \text{ MeV.} \]\[ l_m = -1 \] \( m(-1, 3) = m(-1, 3/2) \) - Comports with the equation underlying the main calculation.\[ m(l_m, 3/2) \] pertains - regarding elementary fermions - for \( l_m \leq -1 \).\[ \text{Neutrinos} \] We suggest masses for the three 0.5N neutrinos. People suggest - based on observations - that the sum of the three neutrino rest energies is at least approximately \( 0.06eV/c^2 \) and not more than approximately \( 0.12eV/c^2 \). People suggest that astrophysics data suggests that at least two distinct masses pertain. We offer two possibilities.\[ \bullet \ mc^2 = m(-4, 3/2)c^2 \approx 3.4 \times 10^{-2} \text{ eV pertains for each of the three neutrinos.} \] Aspects related to 3G and 4G might account for a perception that more than one mass must pertain. (Interactions between 2G and an elementary fermion conserve the mass of the elementary fermion, but do not necessarily conserve the flavour of the elementary fermion. Interactions between 3G and an elementary fermion conserve the flavour of the elementary fermion, but do not necessarily conserve the mass of the elementary fermion. Interactions between 4G and an elementary fermion do not necessarily conserve the mass of the elementary fermion or the flavour of the elementary fermion.)\[ \bullet \ mc^2 = m(-4, 3/2)c^2 \approx 3.4 \times 10^{-2} \text{ eV pertains for each of two neutrinos. For one neutrino, one of } m(-6, 3/2)c^2 \approx 4.2 \times 10^{-6} \text{ eV and } m(-5, 3/2)c^2 \approx 4.4 \times 10^{-4} \text{ eV might pertain.} \]

Table 15: The possibility that - for LRI elementary particles \( \Sigma G \) - \( \Sigma \) might be no greater than four.

<table>

<tr>
<th>Topic</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>( l_m = 18 )</td>
<td>( (q_0)^2/(4\pi \varepsilon_0)) / (G_N(m(18, 3))^2) = 4/3 ).</td>
</tr>
</tbody>
</table>
| Monopole properties | A force strength factor of 4 seems to associate with 1g1 and a force strength factor of 3 seems to associate with 2g2. (See, above, the equation \( (4/3) \times (\beta^2)^0 = ((q_0)^2/(4\pi \varepsilon_0)) / (G_N(m)^2) \)\). Possibly, other force strength factors would be 2 for 3g3, 1 for 4g4, and 0 (or, zero) for 5g5. Possibly, the notion of zero force strength regarding 5g5 associates with a lack of relevance for (and a lack of monopole properties that would associate with) solutions \( \Sigma G \Sigma \) for which \( \Sigma \geq 5 \) and with a lack of LRI elementary particles \( \Sigma G \) for which \( \Sigma \geq 5 \).
3.2. Dark matter

This unit suggests specifications for dark matter.

3.2.1. We discuss - for the six isomers - elementary-fermion masses, flavours, and handedness.

Regarding each $l$ that is at least one, we assume that the elementary particles in isomer $l$ match - with respect to mass - the elementary particles in isomer zero.

For $0 \leq l \leq 5$, we associate the quarks in isomer $l$ with three values of $l_m$. (See table 12 and table 13.) The values are $3l + 0$, $3l + 1$, and $3l + 2$. Across the six isomers, quarks associate with each value of $l_m$ that is in the range $0 \leq l_m \leq 17$. Regarding quarks and flavours, we assume that - within isomer $l$ - flavour 1 associates with $l_m = 3l$, flavour 2 associates with $l_m = 3l + 1$, and flavour 3 associates with $l_m = 3l + 2$.

Aspects of table 12 and table 13 point to the possibility that means for matching flavours and masses for charged leptons do not match means for matching flavours and masses for quarks. For charged leptons, isomer zero does not have a charged lepton that associates with $l_m = 1$ and does have a charged lepton that associates with $l_m = 3$. We assume that - for each $l$ - a charged lepton associates with each of $l_m = 3l + 0$, $l_m = 3l + 2$, and $l_m = 3l + 3$.

We assume that - for each isomer $l$ such that $1 \leq l \leq 5$ - the charged-lepton flavour that associates with $l_m = 3(l) + 0$ equals the flavour that associates with the isomer $l - 1$ charged lepton that associates with the same value of $l_m$ and - thus - with $l_m = 3(l - 1) + 3$. We assume that across the six isomers, one cyclical order pertains regarding flavours for charged leptons.

Table 16 shows, for isomers of charged elementary fermions, matches between masses and flavours.

Beyond the topic of flavours, the topic of handedness exists. Ordinary matter associates with left-handedness. Our modeling suggests the possibility that isomers 0, 2, and 4 associate with left-handedness and that isomers 1, 3, and 5 associate with right-handedness.

Figure 2 interrelates elementary particles, isomers, ordinary matter, and dark matter.

3.2.2. We prepare to discuss the evolution of stuff that associates with each isomer.

We associate the symbol OMSE with all SRI elementary particles and all ELF elementary particles except 0.5M and 0.5R elementary particles. OMSE abbreviates the three-element phrase ordinary-matter-similar elementary particles. We associate the symbol DMAI with the 0.5M and 0.5R elementary particles. DMAI abbreviates the five-word phrase dark matter regarding all isomers. DMAI associates with the notion that - regarding isomer zero - these particles measure as being dark matter and do not measure as being ordinary matter.

We use the three-element term isomer number stuff to denote objects (including SRI elementary particles, ELF elementary particles, hadron-like particles, clumps of stuff, and stars) that associate with the isomer number set of simple elementary particles.

0.5R particles model as entwined. (See table 8.) We suggest that - at least after the inflationary epoch - 0.5R-based stuff consists of hadron-like particles. Each 0.5R-based-stuff hadron-like particle includes gluons and at least two arcs. (We de-emphasize discussing roles that jay bosons might play.) Our work does not suggest an extent to which 0.5R-based stuff might form primordial black holes. Our work does not necessarily suggest that a two-or three-hadron hadron-like particle can include both at least one quark and at least one arc.

0.5M particles model as free. (See table 8)

Regarding each one of the six isomers, we suggest that stuff made from DMAI behaves within bounds for dark matter that associate with concordance cosmology.

3.2.3. We discuss - for each dark matter isomer - the evolution of stuff that associates with that isomer.

We discuss the evolution of isomer 1, 2, 4, and 5 OMSE stuff.

Here, we use the two-word term alt isomer to designate an isomer other than isomer zero and isomer three.

A charged baryon that includes exactly three flavour 3 quarks is more massive than the counterpart zero-charge baryon that includes exactly three flavour 3 quarks. (For example, two tops and a bottom have a larger total mass than do one top and two bottoms.) Alt isomer flavour 3 charged leptons are less massive than isomer zero flavour 3 charged leptons. When flavour 3 quark states are much populated (and based on interactions mediated by W bosons), the alt isomer converts more charged baryons to zero-charge baryons than does isomer zero. Eventually, in the alt isomer, interactions that entangle multiple W bosons result in the alt isomer having more neutrons and fewer protons than does isomer zero. The sum of the mass of a proton and the mass of an alt isomer flavour 1 charged lepton exceeds the mass of a neutron. Compared to isomer zero neutrons, alt isomer neutrons scarcely decay. The IGM (or, intergalactic medium) that associates with the alt isomer scarcely interacts with itself via electromagnetism.
Table 16: Matches between masses and flavours, for isomers of charged elementary fermions. The symbol $0.5Q_{>0}$ denotes the pair $0.5Q_{1/3}$ and $0.5Q_{2/3}$. The symbol $l_f$ numbers the three flavours. (See table 12.)

Figure 9: Elementary particles, isomers, ordinary matter, and dark matter. For counterpart elementary particles (across the six isomers), the masses are the same. Here, the word counterpart refers to positions in the six similar arrays of symbols for elementary particles. For counterpart elementary particles, the magnitudes of the charges are the same. For counterpart leptons, the flavours are not necessarily the same. For each known elementary particle, this figure uses popular symbols. Here - and nowhere else in this essay - the letter $g$ associates with gluons. Here - and nowhere else in this essay - the symbol $\gamma$ associates with the photon.
We discuss the evolution of isomer three OMSE stuff.

The following possibilities pertain. The evolution of isomer three OMSE stuff parallels the evolution of ordinary matter (or, isomer zero OMSE stuff). The evolution of isomer three OMSE stuff does not parallel the evolution of ordinary matter (or, isomer zero OMSE stuff). The second possibility might associate with - for example - a difference in handedness - with respect to charged leptons or with respect to W bosons - between isomer three and isomer zero. (See discussion related to table 16)

3.3. Formation and evolution of the universe

This unit suggests eras - two of which would precede cosmic inflation - in the rate of expansion of the universe and suggest mechanisms that associate with the eras.

3.3.1. We discuss perspective regarding the rate of expansion of the universe.

Concordance cosmology points to three eras in the so-called rate of expansion of the universe. The eras feature, respectively, rapid expansion; continued expansion, with the rate of expansion decreasing; and continued expansion, with the rate of expansion increasing.

This essay suggests using the notion of eras regarding the separating from each other of clumps - that, today, people would consider to be large - of stuff. Examples of such clumps might include galaxy clusters and possibly even larger clumps.

3.3.2. We provide perspective regarding long-range interactions between objects.

As two objects move away from each other, the relative effect of an RDF $\Xi^{-(k+1)}$ component decreases compared to the effect of an RDF $\Xi^{-k}$ component. One might associate the two-word phrase time period with a time range in which an RDF $\Xi^{-l}$ component provides dominant effects. Assuming that objects move away from each other and that one time period associates with $\Xi^{-(k+1)}$ and another time period associates with $\Xi^{-k}$, the time period that associates with $\Xi^{-(k+1)}$ comes before the time period that associates with $\Xi^{-k}$. Two smaller objects (such as galaxies) transit similar time periods more quickly than do two larger objects (such as galaxy clusters).

3.3.3. We discuss known and suggested eras in the history of the universe.

Table 18 suggests details regarding eras to which table 17 alludes.

Before inflation, boson PROP solutions for which $\Sigma \geq 2$ and $8 \in \Gamma$ associate with dominant long-range effects. The word entwined associates with these PROP solutions. After inflation, compared to boson PROP solutions for which $\Sigma \geq 2$ and $8 \notin \Gamma$, boson PROP solutions for which $\Sigma \geq 2$ and $8 \in \Gamma$ do not associate with significant long-range effects. Boson PROP solutions for which $\Sigma \geq 2$ and $8 \in \Gamma$ continue to associate with relevant effects, but just on small (distance) scales. The word free associates with PROP solutions for which $\Sigma \geq 2$ and $8 \notin \Gamma$. Perhaps, a notion of a phase change - for the universe - pertains regarding times around inflation.

Figure 10 interrelates isomers of elementary particles, components of gravity, eras in the evolution of the universe, and eras in the evolution of galaxies. (Regarding galaxies, perhaps preview discussion related to table 19)

3.4. Formation and evolution of galaxies

This unit suggests that our notions regarding long-range interactions and our specifications for dark matter combine to provide insight regarding galaxy formation and galaxy evolution.

3.4.1. We suggest aspects regarding events leading to the formation of a galaxy.

Reference 33 suggests that galaxies form around early clumps of stuff. The reference associates the word halo with such clumps.

Table 17 suggests that single-isomer stuff - such as stuff that features 0.5R particles - forms during an era in which the PROP solution $2g1^23^816$ - which associates with attraction - dominates regarding prototype large clumps. Smaller-scale clumps might form before larger-scale clumps. Effects that associate with the PROP solution $2g1^23$ - which is attractive might contribute to the formation of smaller-scale clumps. The reach that associates with $2g1^23$ is one.

We suggest that each one of many early halos associates with one isomer. We associate with such early halos the three-element term one-isomer original clump. We know of no reason why the six isomers would not form such clumps approximately equally. (Concordance cosmology suggests that known elementary fermions form early in the era in which effects that associate with $2g1^23$ dominate regarding large-scale phenomena. Per remarks above, we suggest that that era starts after the formation of halos. Also, we suggest that our scenario does not depend on whether or when 0.5M particles first form.)

Table 19 discusses suggestions regarding the formation and early evolution of a galaxy for which a notion of a one-isomer original clump pertains.
Table 17: Eras regarding the rate of separating of large clumps. The rightmost two columns suggest eras. (Table 18 discusses aspects that associate with each of some rows.) Subsequent rows associate with later eras. The word inflation names the era that associates with the third row in the table. Regarding eras that would precede inflation, our modeling points to the possibility for the two eras that the table discusses. Concordance cosmology suggests inflation and the next two eras. Regarding inflation, people hypothesize this era. People suggest that the inflationary era started about $10^{-36}$ seconds after the Big Bang. People suggest that the inflationary era ended between $10^{-33}$ seconds after the Big Bang and $10^{-32}$ seconds after the Big Bang. Possibly, no direct evidence exists for this era. Observations support the notions of the two billions-of-years eras. TBD denotes to be determined. The symbol † denotes a possible association between the relevant era and the notion of a Big Bang. The leftmost four columns describe phenomena that our modeling suggests as noteworthy causes for the eras. (Regarding phenomena that associate with gravitation, table 17 echoes aspects - including aspects regarding attraction and repulsion - that table 5 and table 9 show.) An RDF associates with the PROP solution. Generally, a noteworthy cause associates with notions of acceleration. Generally, an era associates with a range of velocities. A noteworthy cause may gain prominence before an era starts.

<th>Rate of separating</th>
<th>Note</th>
</tr>
</thead>
</table>
| Is negative        | Possibility: 2g1'2'3'8'16 and its compacting of “some form of energy” lead to conditions suitable for the universe to form and evolve. Possibility: The value of six for $\rho_I$ associates with setting up a system for which roughly equal creation of isomers pertains. Possibility: Isomers of 0.5R and 1J form. Possibility: The following interactions might characterize this era. For each interaction, the net circular polarization for each of before and after the interaction might be zero. Presumably, the formation of gluons (or, 1(1)U) could associate with the formation of arcs (or, 0.5(1)R).
  - $2(6)g1'2'3'8'16 + 2(6)g1'2'3'8'16 \rightarrow 0.5(1)R + 0.5(1)R$.  
  - $2(6)g1'2'3'8'16 + 2(6)g1'2'3'8'16 \rightarrow 1(1)J + 1(1)J$. Possibility: The six isomers of 0.5R populate approximately equally. Possibility: Some clumps of 0.5R stuff serve - eventually - as seeds for galaxies. Possibility: 1.5R bosons stop the implosion of stuff that is significantly 0.5R particles. Possibility: Isomers of 0.5R form. The following interaction might characterize this era. Here, the net circular polarization for each of before and after the interaction might be two.
  - $1(1)J + 1(1)J \rightarrow 2(1)g1'2'3'4x + 0(1)I$. Possibility: The six isomers of 0.5R populate approximately equally. Possibility: Aspects of this era associate with notions of a Big Bang. 
| Turns positive | 0g1'3'4'8 associates with the 1J (or, jay) boson. The jay boson associates with the notion of Pauli repulsion. Possibility: 1J bosons stop the implosion of stuff that is significantly 0.5R particles. Possibility: Isomers of 0.5R form. The following interaction might characterize this era. Here, the net circular polarization for each of before and after the interaction might be two.
  - $0(1)I + 2(1)g1'2'3'4x \rightarrow 0(1)I + 2(1)g1'2'3'4y$. Possibility: Some concordance cosmology modeling suggests that inflations provide the major component of stuff. Possibility: The following interaction might characterize this era. Here, the net circular polarization for each of before and after the interaction might be two.
  - $0(1)I + 2(1)g1'2'3'4x \rightarrow 0(1)I + 2(1)g1'2'3'4y$. Possibility: Some concordance cosmology modeling suggests that the first significant appearance of most known elementary particles occurs early in this era. Possibility: Some concordance cosmology modeling suggests that the first significant appearance of most known elementary particles occurs early in this era. 
| Increases rapidly | Some concordance cosmology modeling suggests that inflations provide the major component of stuff. Possibility: The following interaction might characterize this era. Here, the net circular polarization for each of before and after the interaction might be two.
  - $1(1)J + 1(1)J \rightarrow 2(1)g1'2'3'4x + 0(1)I$. Possibility: The six isomers of 0.5R populate approximately equally. Possibility: Aspects of this era associate with notions of a Big Bang. 
| Increases | - |
| Would decrease | This essay does not try to explore the possibility that (or to estimate a time at which) a transition - for the largest observable objects - from repulsion based on $2g2'$ to attraction based on $2g2$ might occur.

30
Isomers, gravity, eras regarding the universe, and eras regarding galaxies
(Including driving forces that led to eras in the history of the universe and eras regarding galaxy formation)

Table 19: Stages and other information regarding the evolution of a galaxy for which a notion of a one-isomer original clump pertains. The table suggests stages, with subsequent rows associating with later stages. The rightmost one column describes aspects of the stage. The leftmost four columns in the table describe a component of 2G that is a noteworthy cause for the stage. (Regarding phenomena that associate with gravitation, table 5 and table 9 show.) Table 19 associates with a scenario in which a galaxy forms based on one original clump and does not significantly collide with other galaxies. The galaxy might retain some stuff that associates with the repelled isomer.

Presumably, some galaxies form based on two or more clumps, for which all of the clumps associate with just one isomer. Presumably, some galaxies form based on two or more clumps, for which some clumps associate with isomers that are not the same as the isomers that associate with some other clumps.

3.4.2. We suggest aspects regarding the evolution of galaxies.

We suggest two eras regarding the evolution of galaxies. The first era associates with the first two rows in Table 19. The second era associates with the third row in Table 19. The second era associates with the \(2g_2\) attractive force that associates with the third row in Table 19. We discuss three cases. (Mixed cases and other cases might pertain.)

- Each of some era one galaxies does not collide with other galaxies. Such a galaxy accumulates (via \(2g_2\) attraction) stuff associated with various isomers that have representation in nearby IGM (or, intergalactic medium). The galaxy becomes an era two galaxy. The galaxy might include stuff that significantly associates with as many as five isomers.

- Each of some era two galaxies merges (via \(2g_2\) attraction) mainly just with galaxies that feature the same five isomers. The galaxy that merged, in effect, loses its status of being a galaxy. The resulting larger object is an era two galaxy. The galaxy might include stuff that significantly associates with as many as five isomers.

- Each of some era one or era two galaxies merges (via \(2g_2\) attraction) with other galaxies. The galaxy that merged, in effect, loses its status of being a galaxy. The resulting larger object is an era two galaxy. The galaxy might include stuff that significantly associates with as many as six isomers.

3.4.3. We suggest an explanation for the quenching of star formation within some galaxies and the stopping of the accrual of matter by some galaxies.

People report the notion that some galaxies seem to stop forming stars. (See reference [36] and reference [40].) Such so-called quenching might take place within three billion years after the Big Bang. They might associate with a relative lack of hydrogen atoms, and might pertain to half of a certain type of galaxy. (See reference [34].) Reference [38] discusses a galaxy that seems to have stopped accruing both ordinary matter and dark matter about four billion years after the Big Bang.

We suggest that the quenching and the stopping of accruing nearby matter might associate with repulsion that associates with \(2(2)g^2\). Quenching might associate with galaxies for which original clumps featured isomer zero stuff or isomer three stuff. The galaxy that reference [35] discusses might (or might not) associate with the notion of significant presence early on of one of isomers zero and three, one of isomers one and four, and one of isomers two and five. Such early presences might associate with a later lack of nearby stuff for the galaxy to accrue.

3.4.4. We suggest an explanation for some data regarding stellar stream GD-1 in the Milky Way galaxy.

Data regarding stellar stream GD-1 suggest the possibility of effects from a yet-to-be-detected non-ordinary-matter clump - in the Milky Way galaxy - with a mass of \(10^6\) to \(10^8\) solar masses. (For data and discussion regarding the undetected object, see references [39] and [40].) We suggest that the undetected object might be a clump of dark matter.

3.5. Ratios of dark matter effects to ordinary matter effects

This unit shows that our specification for dark matter seems to explain observed ratios of dark matter effects to ordinary matter effects.

Table 20 provides explanations for observed ratios of dark matter effects to ordinary matter effects. (For data and discussion regarding densities of the universe, see reference [8].) For data and discussion regarding galaxy clusters, see references [11], [12], [13], and [14]. For data and discussion regarding absorption of CMB, see references [15], [16], and [17]. For data and discussion regarding observed early galaxies, see references [18] and [19]. Reference [43] influenced our choice of a time range to associate with the word early. For data and discussion regarding the combination of 0°:1 and later, see references [20], [21], [22], [23], [24], and [25]. For data and discussion regarding observed dark matter galaxies, see references [26], [27], and [28]. Current techniques might not be capable of observing early dark matter galaxies. References [29] and [30] suggest, regarding galaxy clusters, the existence of clumps of dark matter that might be individual galaxies. Extrapolating from results that references [23] and [19] discuss regarding ultrafaint dwarf galaxies that orbit the Milky Way galaxy might suggest that the universe contains many DM:OM 1 : 0° later galaxies. For data and discussion regarding galaxies for which ratios of \(\sim 4:1\) pertain, see references [31] and [32]. For data
Table 20: Explanations for observed ratios of dark matter effects to ordinary matter effects. DM denotes dark matter. OM denotes ordinary matter. DM:OM denotes a ratio of dark matter effects to ordinary matter effects. Inferences of DM:OM ratios come from interpreting data. Regarding densities of the universe, we posit that DMAI stuff associates with the plus in DM:OM $5^+ : 1$. Stuff - other than DMAI stuff - that associates with isomer one through five associates with the five in DM:OM $5^+ : 1$. Regarding some galaxy clusters, we posit that galaxy clusters (that have not collided with other galaxy clusters) associate with DM:OM ratios that are similar to DM:OM ratios for densities of the universe. The four-word phrase some absorption of CMB associates with the notion that people measured some specific depletion of CMB (or, cosmic microwave background radiation) and inferred twice as much depletion as people expected based solely on hyperfine interactions with hydrogen atoms. Possibly, half of the depletion associates with DM effects. We posit that isomer three hydrogen-like atoms account for the half of the absorption for which isomer zero (or, ordinary matter) hydrogen atoms do not account. (See table §A.) The reach of an instance of $1g3_{3/2}$ is two isomers. (See table §A.) Possibly, this occurrence of $4 \in \Gamma$ associates with spin and with hyperfine transitions. Regarding galaxies, the notion of early associates with observations that pertain to galaxies that people associate with (or, would, if people could detect the galaxies, associate with) high redshifts. High might associate with $z > 7$ and possibly with smaller values of $z$. Here, $z$ denotes redshift. The word later associates with the notion that observations pertain to objects later in the history of the universe. The three-word phrase dark matter galaxy denotes a galaxy that contains much less ordinary matter than dark matter. Possibly, people have yet to directly detect early dark matter galaxies.

4. Discussion

This unit discusses some possibilities regarding specific possible elementary particles and regarding dark matter; discusses relationships between our modeling and other modeling; and discusses some aspects regarding so-called “tensions” regarding large-scale phenomena.

We associate the two-word term extant modeling with modeling - including Standard Model modeling and concordance cosmology modeling - that other people developed.

4.1. Some hypothesized elementary particles

This unit discusses possibilities regarding the existence and properties of some hypothesized elementary particles.

4.1.1. We discuss the possible existence of axions.

This essay seemingly does not suggest an elementary boson that would associate with notions of an axion. People suggest that, under some circumstances - axions might convert into photons. We suggest that observations that people might associate with effects of axions might instead associate with the difference between our notion of $1(6)g1^24$ and extant modeling notions that might associate with notions of $1(1)g1^24$. Also, observations that people might associate with effects of axions might instead associate with interactions involving jay (or, 1J) bosons or aye (or, 1I) bosons. (See table [15].)

4.1.2. We discuss the possible existence of magnetic monopoles.

This essay does not suggest an elementary particle that would associate with notions of a magnetic monopole. Table [1] and table [3] seem not to suggest a 1G interaction with a monopole other than an electric monopole.

4.1.3. We develop modeling that might associate with the fraction of right-handed $W$ bosons that one type of quark decay might produce.

Aspects related to table [15] and table [14] suggest values of calculated masses that do not associate with masses of known or suggested elementary particles. For example, our modeling does not suggest that $m(5,3)$ associates with the inertial mass of an isomer one charged lepton. However, perhaps such mass-like quantities associate with some measurable aspects of nature. For charged leptons and $0 \leq l \leq 4$ and $0 \leq l' \leq 2$, $m(3(l + 1) + l', 3) = \beta m(3(l + 0) + l', 3)$. One might conjecture that isomer zero observations of some aspects of isomer one phenomena associate with notions of non-inertial mass-like quantities that are $\beta$ times the inertial masses for isomer zero elementary particles (and that are $\beta$ times inertial masses for the counterpart isomer one elementary particles).

Furthermore, isomer one might associate with right-handedness in a manner similar to the association of isomer zero with left-handedness. (See discussion related to table [16].)

Reference [65] discusses the fraction of decays - of ordinary matter top quarks for which the decay products include $W$ bosons - that might produce right-handed $W$ bosons. The fraction, $f_+$, is $3.6 \times 10^{-4}$. Reference [8] provides a confidence level of 90 percent that the rest energy of a $W_R$ (or, right-handed $W$ boson) exceeds 715 GeV. (Perhaps, note also, reference [66].)

Based on notions of scaling that might calculate non-inertial mass-like quantities, one might conjecture that our modeling suggests that $f_+ \approx e^{(\beta - 1)} - 1 \approx \beta - 1 \approx 2.9 \times 10^{-4}$. This estimate might not be incompatible with results that reference [65] discusses. A notion of $m_{non-inertial,W_{isomer,one}}c^2 = \beta m_Wc^2 \approx 2.8 \times 10^3$ GeV might pertain. Here, the notion of non-inertial mass-like quantity might associate with inferences that associate with 1G or 1W and do not associate directly with 2G.

4.2. Interactions involving the jay boson

This unit discusses interactions that involve jay bosons.

4.2.1. We discuss interactions - that involve jay bosons - that might take place before or during inflation.

We consider interactions in which two jay bosons move in parallel, interact, and produce one aye boson plus something else. Here, we assume that conservation of angular momentum pertains and that one can de-emphasize orbital angular momentum. We consider two cases. In the first case, the two jay bosons have the same (one of either right or left) circular polarization. Conservation of angular momentum allows an outgoing combination of one 2G particle and one 0I particle. Conservation of angular momentum precludes producing one 1G particle and one 0I particle. In the second case, one jay boson has left circular polarization and the other jay boson has right circular polarization. Conservation of angular momentum allows the production of two 0I particles and prohibits the production of one 1G particle and one 0I particle.

The two cases might comport with notions that gravitation can be significant during inflation and that electromagnetism might become significant essentially only after inflation. The two cases might
comport with the notion that jay bosons form before jay bosons form. (See table [58].)

4.2.2. We discuss the notion of Pauli repulsion.

Extant modeling includes the notion that two identical fermions cannot occupy the same state. Regarding extant modeling, one notion is that repulsion between identical fermions associates with overlaps of wave functions. Another notion features wave functions that are anti-symmetric with respect to the exchange of two identical fermions.

Our modeling might be compatible with such aspects of extant modeling and, yet, not necessitate - for kinematics modeling - the use of wave functions. Modeling based on jay bosons might suffice.

Modeling based on jay bosons might suggest that prevention of two identical fermions from occupying the same state might associate with, in effect, trying to change aspects related to the fermions. Notions of changing a spin orientation or, for elementary fermions, changing a flavour might pertain.

4.2.3. We discuss so-called Pauli crystals.

Reference [67] and reference [58] report detection of Pauli crystals. We suggest that modeling based on the notion of jay bosons might help explain relevant phenomena.

4.2.4. We discuss a possible discrepancy - regarding energy levels in positronium - between extant modeling and observation.

Reference [29] and reference [20] discuss the transition - between two states of positronium - characterized by the expression $2^3S_1 \rightarrow 2^3P_0$. People discuss the energy that associates with the transition. Four standard deviations below the nominal observed value of energy approximately equals four standard deviations above the nominal value of energy that extant modeling suggests.

Perhaps, notions regarding jay bosons extend to explain the might-be discrepancy regarding positronium. (For example, thinking of extant modeling based on the Dirac equation, a notion of virtual charge exchange or virtual flavour change might pertain.)

To the extent that extant modeling does not suffice, modeling related to the jay boson might close the gap between observation and modeling.

4.3. Constraints regarding dark matter

This unit discusses the extent to which our notion of dark matter complies with constraints - about the nature of dark matter - that people associate with data about dark matter or with outputs from extant models that have bases in assumptions about dark matter.

4.3.1. We discuss aspects related to cosmological models.

Reference [35] summarizes some thinking about constraints on dark matter and about notions of dark matter. The article notes that so-called CDM (or, cold dark matter) might comport well with various models. Some models associate with the one-element term ΛCDM. The article notes that people have yet to determine directly whether nature includes CDM stuff. The article notes that people consider that notions of SIDM (or, self-interacting dark matter) might be appropriate regarding nature. People also use other terms, such as the three-word term warm dark matter, to note possible attributes of dark matter. Notions such as SIDM and WDM (or, warm dark matter) arose from modeling that differs from our modeling. We are reluctant to try to closely associate terms such as SIDM or WDM with our modeling. (We suggest that isomer zero 0.5R-based stuff, isomer zero 0.5M stuff, and all stuff associating with isomers one, two, four, and five might comport with some notions of CDM. We suggest that the remaining dark matter stuff - or, isomer three OMSE stuff - might associate with some notions of WDM and with some notions of SIDM.)

We suggest that our notion of dark matter is not necessarily incompatible with constraints - that have bases in cosmological models - on dark matter.

4.3.2. We discuss aspects related to collisions of pairs of galaxy clusters.

In particular we discuss the Bullet Cluster collision of two galaxy clusters. (Reference [71] discusses the Bullet Cluster.) Presumably, observations regarding other such collisions might pertain.

Observations suggest two general types of trajectories for stuff. Most dark matter - from either one of the clusters - exits the collision with trajectories consistent with having interacted just gravitationally with the other cluster. Also, ordinary matter stars - from either cluster - exit the collision with trajectories consistent with having interacted just gravitationally with the other cluster. However, ordinary matter IGM (or, intergalactic medium) - from either cluster - lags behind the cluster’s ordinary matter stars and dark matter. That ordinary matter IGM interacted electromagnetically with the other cluster’s ordinary matter IGM, as well as gravitationally with the other cluster.

Our work suggests that - regarding each cluster - essentially all dark matter - except isomer three IGM - passes through without interacting significantly electromagnetically with stuff from the other cluster. Our work suggests that isomer three IGM that associates with each cluster might interact significantly with isomer three IGM that associates with the other cluster. Isomer three IGM might
follow trajectories similar to trajectories for isomer zero IGM.

We are uncertain as to the extent to which observational data might suggest that the amounts of dark matter that lags the bulk of dark matter is sufficiently small that our nominal notions regarding isomer three IGM do not comport with observations. Should the actual fraction of lagging dark matter be too small, we might need to reconsider the extent to which isomer three differs from isomer one. We note some examples of possible reconsideration. For one example, possibly isomer three has right-handed elementary fermions but interactions involving such fermions model as retaining aspects of left-handed-centric interactions that associate with isomer zero. For another example, possibly isomer three does not evolve adequately similarly to isomer zero. To the extent that isomer three adequately differs from or does not evolve similarly to isomer zero, our explanation regarding CMB depletion - in part - interactions with dark matter hydrogen-like atoms might be inaccurate (for example, based on an inaccurate estimate of the number of isomer three hydrogen-like atoms).

We suggest that our notion of dark matter is not necessarily incompatible with constraints - that have bases in observations of collisions of galaxy clusters - on dark matter.

4.4. Data-and-modeling “tensions” regarding large-scale phenomena

This unit suggests means to resolve so-called tensions - between data and extant modeling - regarding the rate of expansion of the universe and other large-scale phenomena.

4.4.1. We explore the extent to which general relativity and the case of \( n_1 = 6 \) are mutually compatible.

Regarding general relativity and the case of \( n_1 = 6 \), the notion of geodesic motion would not necessarily pertain.

For example, consider an isomer zero star and three possible planets. The planets are identical except that one planet associates with isomer zero, one planet associates with isomer one, and one planet associates with isomer three. The planets start out on identical orbits. We consider six cases. First, we assume that the star is spherically symmetric and does not rotate. Out of the \( 2g \) components - only \( 2(6)g \) pertains. The planets traverse identical orbits. Second, we assume that the star rotates. Here, \( 2(2)g \) associates with nonzero effects. The isomer one planet orbits as if \( 2g^2 \) does not pertain. The isomer zero planet and the isomer three planet traverse a trajectory that differs from the trajectory that is common for the previous four cases.

Similarly, regarding general relativity and the case of \( n_1 = 6 \), the notion of a stress-energy tensor (and possibly non-zero cosmological constant) that does not consider isomers and that, in effect, governs all motion would not necessarily pertain. Lack of pertaining might echo the above discussion regarding a star and a planet.

4.4.2. We suggest an explanation for the notion that concordance cosmology underestimates recent increases in the rate of expansion of the universe.

Table 17 and table 18 discuss possible and known eras in the history of the universe.

People suggest that concordance cosmology modeling underestimates - for the second multi-billion-years era - increases in the rate of expansion of the universe. (See references [19], [20], [21], [22], [23], and [24].)

We suggest the following explanation for such underestimates.

When using modeling based on general relativity, people might try to extend the use of an equation of state (or use of a cosmological constant) that works well regarding early in the first multi-billion-years era. Regarding that time, our modeling suggests dominance by attractive effects that associate with the \( 2g^1 \cdot 2^1 \cdot 3^1 \) component of gravity. The notion of a reach of one pertains. The symbol \( 2(1)g^1 \cdot 3^1 \) pertains. Our modeling suggests that - later in the first multi-billion-years era - repulsive effects that associate with \( 2(2)g^2 \cdot 4^1 \) become significant. Dominance by \( 2(2)g^2 \cdot 4 \) pertains by the time the second multi-billion-years era starts. However, people’s use of an equation of state that has roots in the time period in which \( 2(1)g^1 \cdot 2^1 \cdot 3^1 \) dominates would - at best - extrapolate based on a notion of \( 2(1)g^2 \cdot 4^1 \) (and not a notion of \( 2(2)g^2 \cdot 4 \)). That modeling would understate the strength of the key driver - of expansion - by a factor of two.

We point - conceptually - to the following possible remedy.

People might change (regarding the stress-energy tensor or the cosmological constant) the aspects that would associate with repulsion and the \( 2g^2 \cdot 4 \) component of gravity. The contribution - to the pressure - that associates with \( 2g^2 \cdot 4 \) needs to double (compared to the contribution that would associate with \( 2(1)g^2 \cdot 4 \)).

4.4.3. We suggest an explanation for the notion that concordance cosmology overestimates large-scale clumping of matter.

People suggest that concordance cosmology modeling overestimates large-scale clumping of matter - ordinary matter and dark matter. (For
data and discussion, see references [21], [20], [71], and [22].

We suggest that concordance cosmology modeling associates with a repulsive component - 2(1)g2`4 - of gravity. Our modeling suggests that 2(2)g2`4 pertains. (That is, for each instance of 2g2`4, a reach of two isomers pertains.) The additional (compared to concordance cosmology modeling) repulsion might explain the overestimating - of clumping, per concordance cosmology modeling - that people suggest.

4.4.4. We suggest an explanation for the notion that concordance cosmology might not account for some observations about effects - within individual galaxies - of the gravity associated with nearby galaxies.

People suggest that concordance cosmology modeling might not account for some observations about effects - within individual galaxies - of the gravity associated with nearby galaxies. (For data and discussion, see reference [23].)

We suggest that concordance cosmology modeling associates with a repulsive component - 2(1)g2`4 - of gravity. Our modeling suggests that 2(2)g2`4 pertains. The additional (compared to concordance cosmology modeling) repulsion might explain at least some aspects of the observations that people report.

4.5. Some modeling regarding elementary particles

This unit discusses possible symmetries and modeling regarding elementary particles.

4.5.1. We point to the possibility that an approximate symmetry might pertain regarding families of simple elementary particles.

Table 21 lists the families of simple elementary particles.

For each row in table 21, the number of families that associate with free equals the number of families that associate with entwined.

This essay does not further explore notions that an approximate symmetry might pertain.

4.5.2. We discuss possibilities regarding modeling for light that does not propagate completely freely.

Discussion elsewhere in this essay de-emphasizes the topic of modeling that might associate - for light - with confinement or with refraction. Examples of relevant phenomena might include excitations and de-excitations of electromagnetic modes in a laser, the Casimir effect, and excitations and de-excitations of electromagnetic modes in a fiber-optic cable.

Table 22 shows some possible CURR ΣgΓ solutions for which 32 ∈ Γ. (The first three PROP Σg solutions appear in table 3.)

Possibly, the following notions pertain regarding some PROP-and-CURR pairs for which - for the CURR solution - 32 ∈ Γ. Momentum associates with 32 ∈ Γ. For modes for a laser, momentum associates with characteristics of the relevant cavity. People might develop useful modeling based on such concepts.

This essay does not pursue such notions further.

4.5.3. We discuss a possible association between our modeling and SU(3) × SU(2) × U(1) symmetries that extant modeling associates with known elementary bosons.

Extant modeling associates SU(3) × SU(2) × U(1) symmetries with modeling for the known elementary bosons, except the Higgs boson. We are uncertain as to the extent that people should expect that our modeling points to such symmetries.

We explore one way that our modeling might point to such symmetries.

Extant modeling associates a U(1) symmetry with the photon. U(1) associates with mathematics that associates with a one-dimensional harmonic oscillator, 2G associates with one elementary particle. For each polarization handedness, excitation amplitudes associate with modeling for a one-dimensional harmonic oscillator.

Extant modeling associates an SU(2) × U(1) symmetry with the weak-interaction bosons (1Z and 1W1). Extant modeling associates the notion of broken symmetry with the SU(2) aspect. For each polarization handedness, excitations can associate with each of three bosons - the Z, the W+, and the W−. Three is the number of generators that associates with SU(2). The difference between the mass that associates with 1Z and the mass that associates with 1W1 might associate with a break in the SU(2) symmetry. For each combination of polarization handedness and choice from among the three bosons, excitations that associate with a one-dimensional harmonic oscillator and a U(1) symmetry might pertain.

Extant modeling associates an SU(3) symmetry with gluons. Notions parallel to notions just discussed might suggest an SU(3) × U(1) symmetry. To the extent that the U(1) symmetry is not appropriate, the lack of appropriateness might associate with the notion that entwined associates with gluons and not with the weak interaction bosons and not much with the photon.

This essay does not pursue this discussion further (for example, to include the Higgs boson, to point to conservation laws, or to point mathematically to possibly relevant manifolds).

4.6. Relationships between our modeling and other modeling

This unit discusses some possible relationships between our modeling and types of extant models.
4.6.1. We suggest approximate relationships between some extant modeling and aspects of our modeling regarding properties.

Table 22 discusses approximate relationships between modeling that can deploy elementary-particle properties and aspects of our modeling.

4.6.2. We discuss aspects related to the value of two for each (or, ρ₁).

This essay suggests that ρ₁ = 2 pertains for some components of long-range interactions (or, LRI). This essay suggests that the notion of ρ₁ = 2 might have importance regarding explaining data regarding the following - some depletion of CMB, large-scale clumping, the recent multi-billion-years era of increases regarding the rate of separation of large clumps, gravitational interactions between neighboring galaxies, and galaxy formation.

5. Conclusions

This unit summarizes aspects of our work and suggests perspective about our work.

5.1. Our modeling

Our modeling features two bases.

One basis unifies and decomposes aspects of electromagnetism and gravity. For each of electromagnetism and gravity, the decomposition seems to associate well with properties - of objects - that people can measure and that extant modeling features. For electromagnetism, the properties include charge and magnetic moment. For gravity and kinematics related to mass, the properties include mass and moments of inertia.

One basis features isomers of elementary particles that do not intermediate long-range interactions and features instances of components of long-range interactions.

Our modeling extends from the two bases to do the following. Match all known elementary particles and suggest possible other elementary particles. Describe dark matter. Point to explanations for data that extant modeling seems not to explain. Suggest data that might associate with future observations.

We suggest the possibility that the notion that our work explains phenomena that extant modeling does not explain points to usefulness for our work. We explain quantitatively eight quantitative data points or approximate data ranges regarding observed ratios of dark matter effects to ordinary matter effects. (See table 20.) Some other explanations have quantitative bases but - to the extent that this essay uses the explanations - are qualitative. Presumably, people can use simulations to help verify or refute some of our qualitative explanations. Generally, we know of no cases in which our suggestions that address possible gaps between extant modeling and observations point - compared to extant modeling - in a wrong direction regarding closing gaps.

We suggest the possibility that the notion that our work suggests specifications and data that extant modeling does not suggest points to possible usefulness for our work. Our suggestions include a specification for dark matter, specifications for new elementary particles, and more (than current measurements provide) accurate masses for neutrinos and some other known elementary particles.

We suggest that the small set of bases for our modeling, the breadth of seemingly coherent scope of our modeling, the simplicity of relevant Diophantine equations, and the possible ease of integrating our modeling and extant modeling point to possible usefulness for our work.

5.2. Our work

Our work suggests augmentations - to physics modeling - that produce results that may provide progress regarding the following physics opportunities. Complete the list of elementary particles. Describe dark matter. Explain ratios of dark matter to ordinary matter. Explain eras in the history of the universe. Link properties of objects. Interrelate physics models.
Table 23: Approximate relationships between modeling that can deploy elementary-particle properties and aspects of our modeling. \( n_1 \) denotes a number - one or six - of isomers. Extant modeling associates with \( n_1 = 1 \). Each one of some of the items in the symbol column does not associate with an extant modeling symbol. The symbol NNR denotes the three-word phrase not necessarily relevant. Regarding NEW, the symbol NNR associates with the notion that mass does not vary with velocity. Regarding CNC, \( 1g1 \) associates with charge and \( 1g17 \) associates with current. No other components have relevance. CNC associates with charge-current 4-vectors and with Maxwell’s equations. Compared to CNC, QED adds associations with magnetic fields created by other than charge currents and associated with anomalous magnetic moments. QCD associates with \( 0.5Q^{1/3} \) and \( 0.5Q^{2/3} \). We suggest the possibility that QCD might extend to associate with \( 0.5R \).

</table>

We use our modeling to match data that other modeling matches.

We use our modeling to suggest explanations for data that other modeling seems not to explain.

We use our modeling to suggest results regarding data that people have yet to gather.

The breadth and depth of the matched data might suffice to justify using our modeling.

The breadth and unity - within itself and with physics modeling that people use successfully - of our modeling might support the usefulness of our modeling.

Acknowledgments

The following people pointed, via personal contact, to topics or aspects that we considered for inclusion in the scope of our work: Andrea Albert, Raphael Bousso, Lance Dixon, Persis Dreil, Immanuel Freedman, Ervin Goldfain, Vesselin Gueorguiev, Kamal Melek Hanna, Wick Haxton, Nick Hutzler, William Luna, Surynd More, Holger Muller, J. Xavier Prochnik, Martin Rees, Harrison Rose, and Mak Tafazoli.

The following people provided comments regarding the effectiveness of drafts that led to parts of this essay: Immanuel Freedman, Ervin Goldfain, Vesselin Gueorguiev, William Luna, Tom Lawrence, and Mak Tafazoli.

The following people helped publish aspects leading to work that this essay describes: Charles K. Chui, Kamal Melek Hanna, Keith Jones, and Zeger Karssen. (Perhaps, note reference [78] and reference [29].) The following people provided or pointed to aspects regarding expressing or propagating the work: Elliott Bloom, Man Ho Chan, Maxwell Chertok, Charles K. Chui, Andrei Lucian Dragoi, Steven Frautschi, Carl Frederick, Ervin Goldfain, Vesselin Gueorguiev, Ioannis Haranas, Richard B. Holmes, Frank Hiroshi Ling, Michael Mullhern, Richard A. Muller, Stephen Perrenoud, Paul Preuss, Anmol Pushp, Amir Sharif, and Wendy Shi. The following people suggested perspective, means, or suggestions regarding people with whom to try to have discussions: Vint Cerf, Yanbei Chen, James S. Clegg, Bill Dauph, Jiggs Davis, George Djorgovski, Erica Ellingson, Ron Fredericks, Vesselin Gueorguiev, Tuckers Haatt, William Luna, Lianne La Reine, Robert Morgan, Doug Osheroff, Kennan Salinero, Jim Spohrer, Peter Walstrom, and Jon F. Wilkins.
